# Preface

At the time of writing this, I am starting my PhD at The Ohio State University. Currently a large part of my interests in algebra are about algorithms as they relate to polynomials and algebraic geometry. I've been doing a bunch of problems from *Ideals, Varieties, and Algorithms* [CLO15]. However, it seems that *Using Algebraic Geometry* [CLO05] moves through the material faster as it assumes you know more algebra. So I've moved onto working through this book as well as trying to comprehend Sturmfel's *Algorithms in Invariant Theory* [Str08].

# Chapter 1

## Introduction

### 1.1 Polynomials and Ideals

**Solution:** [CLO05] Ex. 1.1.1:

- (a) We have that  $x(x - y^2) + y(xy) = x^2 - xy^2 + xy^2 = x^2$ .
- (b) It suffices to check for generators. We have that  $x + (-1)(y^2) = x - y^2$ ,  $y(x) = xy$ , and  $y^2 = y^2$  showing that  $\langle x - y^2, xy, y^2 \rangle \subseteq \langle x, y^2 \rangle$ . Then  $x - y^2 + y^2 = x$  and  $y^2 = y^2$  shows the reverse containment and overall the ideals are equal.
- (c) We already know from 1. that  $x^2$  lives in  $\langle x - y^2, xy \rangle$ . Since  $xy = xy$ , we overall have that  $\langle x^2, xy \rangle \subseteq \langle x - y^2, xy \rangle$ . It remains to check if  $x - y^2 \in \langle x^2, xy \rangle$ . However, notice that every element of  $\langle x^2, xy \rangle$  is divisible by  $x$  while  $x - y^2$  is clearly not divisible by  $x$ . Thus  $x - y^2 \notin \langle x^2, xy \rangle$  and the two ideals are not equal.

□

**Solution:** [CLO05] Ex. 1.1.2: Let  $f, g \in \langle f_1, \dots, f_s \rangle$ . Then  $\exists p_1, \dots, p_s, q_1, \dots, q_s$  such that  $f = \sum_{i=1}^s p_i \cdot f_i$  and  $g = \sum_{i=1}^s q_i \cdot f_i$ . Thus  $f + g = \sum_{i=1}^s (p_i + q_i) \cdot f_i$  which shows that  $f + g \in \langle f_1, \dots, f_s \rangle$ . Then let  $p \in k[x_1, \dots, x_n]$ . We have that  $p \cdot f = p \cdot \sum_{i=1}^s p_i f_i = \sum_{i=1}^s (p \cdot p_i) \cdot f_i$  which shows that  $\langle f_1, \dots, f_s \rangle$  is an ideal. □

**Solution:** [CLO05] Ex. 1.1.3: We already know that  $\langle f_1, \dots, f_s \rangle$  is an ideal by [CLO05] Ex. 1.1.2. Now suppose that  $J$  is an ideal containing  $\{f_1, \dots, f_s\}$ . Then, since ideals are closed under addition and scaling, we have that for all  $p_1, \dots, p_s \in k[x_1, \dots, x_n]$  that  $\sum_{i=1}^s p_i \cdot f_i \in J$ . Thus,  $\langle f_1, \dots, f_s \rangle \subseteq J$ . □

**Solution:** [CLO05] Ex. 1.1.4: We claim that  $\langle f_1, \dots, f_s \rangle = \langle g_1, \dots, g_t \rangle$  if and only if  $\{g_1, \dots, g_t\} \subseteq I$  and  $\{f_1, \dots, f_s\} \subseteq J$ . The forward implication is immediate. Then by [CLO05] Ex. 1.1.3, if  $\{g_1, \dots, g_t\} \subseteq I$  then  $J \subseteq I$ . Similarly,  $\{f_1, \dots, f_s\} \subseteq J \implies I \subseteq J$  and overall  $I = J$ . This fact was used in [CLO05] Ex. 1.1.1 (b). □

**Solution:** [CLO05] Ex. 1.1.5: It suffices to show that  $z - x^3 \in \langle y - x^2, z - xy \rangle$  and  $z - xy \in \langle x - y^2, z - x^3 \rangle$ . Indeed we have that  $(z - xy) + x(y - x^2) = z - x^3$  which also yields that  $z - xy = z - x^3 - x(y - x^2)$ .  $\square$

**Solution:** [CLO05] Ex. 1.1.6: If  $I = \{0\}$  then  $I = \langle 0 \rangle$ . So suppose  $I \neq 0$ . Let  $d \in I$  be of minimal degree.  **$\langle d = \gcd(I)$  but I need infinite Bezout.  $\rangle$**  Then we claim that  $\langle d \rangle = I$ . Since  $d \in I$ , we have that  $\langle d \rangle \subseteq I$ . Now let  $f \in I$ . By Euclidean division, there exists  $q, r \in k[x]$  such that  $f = qd + r$  where either  $r = 0$  or  $0 \leq \deg(r) < \deg(d)$ . If  $r = 0$  then  $f \in \langle d \rangle$  and we are done. So suppose  $r \neq 0$ . Then  $f, qd \in I \implies r = f - qd \in I$ . Thus,  $r \in I$  is of degree strictly less than  $d$ , contradicting the minimality of the degree of  $d$ . So we must have that  $r = 0$  and overall  $\langle d \rangle = I$ .  $\square$

**Solution:** [CLO05] Ex. 1.1.7:

(a) Suppose  $f(x) \in \langle x \rangle$ . Then  $f(x)^m \in \langle x^n \rangle$  so  $f(x) \in \sqrt{\langle x^n \rangle}$ . Now suppose that  $f(x) \in \sqrt{\langle x^n \rangle}$ . Then  $\exists k$  such that  $f(x)^k \in \langle x^n \rangle$ . Thus  $f(x)^k$  is a multiple of  $x^n$ . This implies that  $f(x)^k$  is a multiple of  $x$ . Then notice that the unique factorization of  $f(x)^k$  into irreducibles is the  $k$ th power of the factorization of  $f(x)$  into irreducibles. Thus  $x$  must be a factor of  $f(x)$  and so  $f(x) \in \langle x \rangle$ . Note, this heavily uses the fact that  $k[x]$  is a unique factorization domain for all fields  $k$ .

(b) We claim that  $\sqrt{\langle p(x) \rangle} = \langle (x - a_1) \cdots (x - a_m) \rangle = I$ . Suppose  $f(x) \in I$ . Let  $k = \max e_1, \dots, e_n$ . Then  $p(x) \mid f(x)^k$  so  $f(x) \in \sqrt{\langle p(x) \rangle}$ . Now suppose that  $f(x) \in \sqrt{\langle p(x) \rangle}$ . Then  $\exists k$  such that  $f(x)^k \in \langle p(x) \rangle$ . Thus  $f(x)^k$  is a multiple of each  $(x - a_i)$ . Then notice that the unique factorization of  $f(x)^k$  into irreducibles is the  $k$ th power of the factorization of  $f(x)$  into irreducibles. Thus  $f(x)$  is a multiple of each  $(x - a_i)$  and so  $f(x) \in I$ .

(c) Radical ideals are the ideals  $I$  such that  $\sqrt{I} = I$ . Notice that  $\mathbb{C}[x]$  is a principal ideal domain and so any such  $I$  must be generated by a single polynomial. Since every polynomial in  $\mathbb{C}[x]$  splits into linear factors, (b) immediately implies that the only radical ideals of  $\mathbb{C}[x]$  are the ones which are of the form  $\langle (x - a_1) \cdots (x - a_m) \rangle$  for  $a_1, \dots, a_m \in \mathbb{C}$ .  $\square$

**Solution: [CLO05] Ex. 1.1.8:**

- (a) Let  $\mathfrak{p}$  be a prime ideal in  $k[\bar{x}]$ . Clearly  $\mathfrak{p} \subseteq \sqrt{\mathfrak{p}}$  always. Let  $f(\bar{x}) \in \sqrt{\mathfrak{p}}$ . Then  $f(\bar{x})^m \in \mathfrak{p}$  for some  $m \in \mathbb{Z}_{\geq 1}$ . We prove the reverse inclusion by induction on  $m$ . If  $m = 1$  then  $f(\bar{x}) = f(\bar{x})^1 \in \mathfrak{p}$ . Now let  $m > 1$  and suppose the claim holds for all  $k \leq m$ . Then suppose  $f(\bar{x})^{m+1} \in \mathfrak{p}$ . Then  $f(\bar{x}) \cdot f(\bar{x})^m \in \mathfrak{p}$ . Either  $f(\bar{x}) \in \mathfrak{p}$  or  $f(\bar{x})^m \in \mathfrak{p}$  which by induction implies that  $f(\bar{x}) \in \mathfrak{p}$ . Thus,  $f(\bar{x})^m \in \mathfrak{p} \implies f(\bar{x}) \in \mathfrak{p}$  for all  $m \in \mathbb{Z}_{\geq 1}$  and so  $\sqrt{\mathfrak{p}} \subseteq \mathfrak{p}$ . Thus, all prime ideals are radical.
- (b) Notice that for all fields  $k$  that  $k[x]$  is a principal ideal domain. Thus, all the prime ideals are the ones generated by a single irreducible polynomial. Also, in  $k[x]$  we have that  $(0)$  is a prime ideal as well as  $k[x]$  is an integral domain. In  $\mathbb{C}[x]$ , these are the ideals generated by  $x - z$  for some  $z \in \mathbb{C}$ . In  $\mathbb{R}[x]$ , the primes are the ideals generated by  $x - r$  for some  $r \in \mathbb{R}$  or  $x^2 + r$  for some positive  $r \in \mathbb{R}$ .  **$\langle \langle$  What would be a general condition for  $\mathbb{Q}[x]$ ?  $\rangle \rangle$**

□

**Solution: [CLO05] Ex. 1.1.9:**

- (a) First, observe that  $\langle x_1, \dots, x_n \rangle$  is the ideal consisting exactly of polynomials which have no constant term. Let  $I$  be an ideal in  $k[x_1, \dots, x_n]$  such that  $\langle x_1, \dots, x_n \rangle \subsetneq I$ . Thus there exists  $f(x_1, \dots, x_n) \in I \setminus \langle x_1, \dots, x_n \rangle$ . We have by our observation that  $f$  has a nonzero constant term  $z$ . Then note that the non-constant terms of  $f$  form a polynomial  $g(x_1, \dots, x_n)$  in  $\langle x_1, \dots, x_n \rangle$ . Thus, we have that  $z = f(x) - g(x) \in I$ . Since  $I$  contains a nonzero constant term, we must have that  $I = k[x_1, \dots, x_n]$ .
- (b) Recall that an ideal  $I$  is maximal if and only if  $R/I$  is a field. Let  $I = \langle x_1 - a_1, \dots, x_n - a_n \rangle$ . Consider the evaluation map  $\text{ev}_{\bar{a}}: k[x_1, \dots, x_n] \rightarrow k$  sending  $f(x_1, \dots, x_n) \mapsto f(a_1, \dots, a_n)$ . Clearly this map is surjective. Then since for all  $i$  we have that  $x_i \equiv a_i \pmod{I}$ , we have that  $f(x_1, \dots, x_n) \equiv f(a_1, \dots, a_n) \pmod{I}$  for all  $f(x_1, \dots, x_n) \in k[x_1, \dots, x_n]$ . Thus,  $\text{ev}_{\bar{a}}(f) = f(a_1, \dots, a_n) = 0$  if and only if  $f(x_1, \dots, x_n) \in I$ . Thus,  $\ker(\text{ev}_{\bar{a}}) = I$  and  $k[x_1, \dots, x_n]/I$  is a field, meaning  $\langle x_1 - a_1, \dots, x_n - a_n \rangle$  is maximal.
- (c) Since  $\mathbb{R}[x]$  is a principal ideal domain, any ideal  $I$  strictly containing  $\langle x^2 + 1 \rangle$  is of the form  $\langle g(x) \rangle$  for some  $g(x) \mid x^2 + 1$ . However, since  $x^2 + 1$  is irreducible in  $\mathbb{R}[x]$ , we have that  $g(x)$  is either  $z(x^2 + 1)$  for some nonzero  $z \in \mathbb{C}$  or  $g(x) = z$  for some nonzero  $z \in \mathbb{C}$ , meaning  $\langle g(x) \rangle = \langle x^2 + 1 \rangle$  or  $\langle g(x) \rangle = \mathbb{R}[x]$ . Thus,  $\langle x^2 + 1 \rangle$  is maximal. However, in  $\mathbb{C}[x]$ , we have that  $x^2 + 1 = (x + i)(x - i)$  and so  $\langle x^2 + 1 \rangle \subsetneq \langle x - i \rangle \subsetneq \mathbb{C}[x]$ .

□

**Solution:** [CLO05] Ex. 1.1.10:

- (a) Since  $x^2 + y^2 - (x^2 - z^3) = y^2 + z^3$  is an element of  $I$  which does not depend on  $x$ ,  $y^2 + z^3$  is in  $I_1$ .
- (b) For all  $\ell \geq 1$ , we have that  $0 \in I_\ell$ . Then, if  $f(x_{\ell+1}, \dots, x_n), g(x_{\ell+1}, \dots, x_n)$  are two polynomials in  $I$  who do not depend on the first  $\ell$  variables, then so is  $f + g$ . Finally, let  $r(x_{\ell+1}, \dots, x_n) \in k[x_{\ell+1}, \dots, x_n]$ . Then  $r \cdot f \in I_\ell$  since  $r \cdot f \in I$  and still does not depend on any of the first  $\ell$  variables.

□

**Solution:** [CLO05] Ex. 1.1.11:

- (a) << meh >>
- (b) << meh >>
- (c) We claim that  $I + J = \langle f_1, \dots, f_s, g_1, \dots, g_t \rangle$ . Clearly  $I, J \subseteq \langle f_1, \dots, f_s, g_1, \dots, g_t \rangle$  and thus so is  $I \cup J$ . By (b), this shows that  $I + J \subseteq \langle f_1, \dots, f_s, g_1, \dots, g_t \rangle$ . Then, since  $f_i = f_i + 0$  and  $g_j = 0 + g_j$  for all  $i, j$ , we have the reverse inclusion and thus the two ideals are equal.

□

**Solution:** [CLO05] Ex. 1.1.12:

- (a) << meh >>
- (b) Suppose that  $h(\bar{x}) \in IJ$ . Note that  $IJ$  is generated by the products  $f(\bar{x}) \cdot g(\bar{x})$  for  $f(\bar{x}) \in I$ , and  $g(\bar{x}) \in J$ . Then  $h(\bar{x})$  consists of sums of terms of the form  $r(\bar{x}) \cdot f(\bar{x}) \cdot g(\bar{x})$  for  $r(\bar{x}) \in k[\bar{x}]$ ,  $f(\bar{x}) \in I$ , and  $g(\bar{x}) \in J$ . Thus, each term is in both  $I$  and  $J$  and overall so is  $h(\bar{x})$ .
- To see an example where  $IJ \subsetneq I \cap J$ , consider  $I = \langle x^2y \rangle$  and  $J = \langle xy^2 \rangle$  in  $k[x, y]$ . Then  $I \cap J = \langle x^2y^2 \rangle$  and  $IJ = \langle x^3y^3 \rangle$ . Thus  $IJ \subsetneq I \cap J$  as  $I \cap J$  contains  $x^2y^2$  and  $IJ$  does not contain  $x^2y^2$ .

□

## 1.2 Gröbner Bases

Solution:  $\langle \text{[CLO05] Ex. 1.3.11} \rangle :$

### 1.3 Affine Varieties

Solution:  $\langle \text{[CLO05] Ex. 1.4.9} \rangle :$

## Chapter 2

# Solving Polynomial Equations

### 2.1 Solving Polynomial Systems by Elimination

Solution:  $\langle\langle$  [CLO05] Ex. 2.1.1  $\rangle\rangle$  :

□

Solution:  $\langle\langle$  [CLO05] Ex. 2.1.2  $\rangle\rangle$  :

□

Solution: [CLO05] Ex. 2.1.3: We may freely rewrite the polynomial as  $p(z) = z^n - a_{n-1}z^{n-1} - \dots - a_0$ . We have that  $0 = \bar{z}^n - a_{n-1}\bar{z}^{n-1} - \dots - a_0$  and so  $\bar{z}^n = a_{n-1}\bar{z}^{n-1} + \dots + a_0$ . Suppose now that  $|\bar{z}| \geq 1$ . Then

$$|\bar{z}|^n = |a_{n-1}\bar{z}^{n-1} + \dots + a_0| \leq |a_{n-1}||\bar{z}|^{n-1} + \dots + |a_0| \leq |a_{n-1}|\bar{z}^{n-1} + \dots + |a_0|\bar{z}^{n-1}.$$

Thus,  $|\bar{z}| \leq |a_{n-1}| + \dots + |a_0|$ . However, we assumed that  $|\bar{z}| \geq 1$ . This may not be the case. Thus,  $|\bar{z}| \leq B := \max\{1, |a_{n-1}| + \dots + |a_0|\}$ . □

Solution:  $\langle\langle$  [CLO05] Ex. 2.1.4  $\rangle\rangle$  : Numerically find all roots of  $2z^6 + 2z^5 - z^4 - z^3 - 2z^2 - 2z - 2$ . □

**Solution:** [CLO05] Ex. 2.1.5: We apply Buchberger's Criterion. Let  $f(x, y) = x^2 + 2x + 3 + y^5 - y$  and  $g(x, y) = y^6 - y^2 + 2y$ . Then we have that

$$S(f, g) = \frac{x^2 y^6}{x^2} \cdot (x^2 + 2x + 3 + y^5 - y) - \frac{x^2 y^6}{y^6} \cdot (y^6 - y^2 + 2y) = y^6 \cdot (x^2 + 2x + 3 + y^5 - y) - x^2 \cdot (y^6 - y^2 + 2y).$$

This shows that  $\overline{S(f, g)}^G = 0$  which yields that  $G$  is a Gröbner basis. □

**Solution:** << [CLO05] Ex. 2.1.6 >> : □

**Solution:** << [CLO05] Ex. 2.1.7 >> : □

**Solution:** [CLO05] Ex. 2.1.8:

- (a) Let  $\bar{z}$  be a simple root of  $p(z)$ , so  $p(\bar{z}) = 0$  but  $p'(\bar{z}) \neq 0$ . Then  $N_p(\bar{z}) = \bar{z} - \frac{p(\bar{z})}{p'(\bar{z})} = \bar{z}$  meaning  $\bar{z}$  is a fixed point of  $N_p(z)$ .
- (b) Suppose that  $\bar{z}$  is a multiple root of  $p(z)$  with multiplicity  $m \geq 2$ . Then we may express  $p(z) = \tilde{p}(z)(z - \bar{z})^m$  such that  $\tilde{p}(\bar{z}) \neq 0$ . Thus, we have that

$$\begin{aligned} N_p(z) &:= z - \frac{p(z)}{p'(z)} \\ &= z - \frac{\tilde{p}(z)(z - \bar{z})^m}{\tilde{p}'(z)(z - \bar{z})^m + m\tilde{p}(z)(z - \bar{z})^{m-1}} = z - \frac{\tilde{p}(z)(z - \bar{z})}{\tilde{p}'(z)(z - \bar{z}) + m\tilde{p}(z)} \end{aligned}$$

Note that  $m\tilde{p}(\bar{z}) \neq 0$ . Thus, we have that

$$|N_p(\bar{z})| = \left| \bar{z} - \frac{\tilde{p}(\bar{z})(\bar{z} - \bar{z})}{\tilde{p}'(\bar{z})(\bar{z} - \bar{z}) + m\tilde{p}(\bar{z})} \right| = |\bar{z}| \leq \text{LC}(p) \cdot B$$

where  $B$  is the value from [CLO05] Ex. 2.1.3 and  $\text{LC}(p)$  is the leading coefficient of  $p(z)$ .

- (c) Suppose now that  $\bar{z}$  is a simple root of  $p(\bar{z})$ . Then we may express  $p(z) = \tilde{p}(z)(z - \bar{z})$  such that  $\tilde{p}(\bar{z}) \neq 0$ . We have that

$$p'(z) = \tilde{p}'(z)(z - \bar{z}) + \tilde{p}(z)$$

and evaluation of  $p'(z)$  at  $\bar{z}$  is nonzero.

- (d) Let  $\bar{z}$  be a root of multiplicity  $m$ . Following (b), we write  $p(z) = \tilde{p}(z)(z - \bar{z})^m$  such that  $\tilde{p}(\bar{z}) \neq 0$ . Then we have, by differentiating the expression for  $N_p(z)$  from (b), that

$$N'_p(z) = 1 - \frac{(\tilde{p}'(z)(z - \bar{z}) + \tilde{p}(z))(\tilde{p}'(z)(z - \bar{z}) + m\tilde{p}(z)) - (\tilde{p}(z)(z - \bar{z}))(\tilde{p}''(z)(z - \bar{z}) + \tilde{p}'(z) + m\tilde{p}'(z))}{(\tilde{p}'(z)(z - \bar{z}) + m\tilde{p}(z))^2}.$$

Evaluation at  $z = \bar{z}$  yields that  $\lim_{z \rightarrow \bar{z}} N'_p(z) = 1 - \frac{1}{m}$ .

- (e) Let  $\bar{z}$  be a root of multiplicity  $m$ . Following (b), we write  $p(z) = \tilde{p}(z)(z - \bar{z})^m$  such that  $\tilde{p}(\bar{z}) \neq 0$ . Then

$$p'(z) = \tilde{p}'(z)(z - \bar{z})^m + m\tilde{p}(z)(z - \bar{z})^{m-1} = (z - \bar{z})^{m-1}(\tilde{p}'(z)(z - \bar{z}) + m\tilde{p}(z)).$$

Notice that  $\tilde{p}'(\bar{z})(\bar{z} - \bar{z}) + m\tilde{p}(\bar{z}) = m\tilde{p}(\bar{z}) \neq 0$ . Thus, a root of multiplicity  $m \geq 1$  of  $p(z)$  is a root of multiplicity  $m - 1$  of  $p'(z)$ . This implies that if we have roots  $\bar{z}_1, \dots, \bar{z}_k$  with multiplicities  $m_1, \dots, m_k \geq 1$ , then  $\gcd(p(z), p'(z)) = (z - \bar{z}_1)^{m_1} \dots (z - \bar{z}_k)^{m_k}$ . Thus, the polynomial  $p_{\text{red}}(z) = \frac{p(z)}{\gcd(p(z), p'(z))}$  has the same roots of  $p(z)$  but all with multiplicity 1 which is the best case for Newton's method.

□

**Solution:** [CLO05] Ex. 2.1.9:

(a) Let  $p(z) = z^2 + 1$ . We have that

$$N_p(z) = z - \frac{z^2 + 1}{2z} = \frac{2z^2 - z^2 + 1}{2z} = \frac{z^2 + 1}{2z} = \frac{x^2 + 2ixy - y^2 + 1}{2x + 2iy}.$$

If  $z$  is real then  $y = 0$  and so  $N_p(x) = \frac{x^2+1}{2x}$  which is always real. Thus, Newton's method will never reach the imaginary roots of  $z^2 + 1$ . However, if we begin with a guess with nonzero imaginary part, then the guess does converge as expected.

(b) **<< Just basic arithmetic not worth doing. >>**

□

**Solution:** [CLO05] Ex. 2.1.10: Let  $\bar{z}$  be a root of  $p(z)$ . Then  $-\bar{z}^n = a_{n-1}\bar{z}^{n-1} + \cdots + a_0$  and so

$$\begin{aligned} |\bar{z}|^n &= |a_{n-1}\bar{z}^{n-1} + \cdots + a_0| \\ &\leq \max_i \{|a_i|\} \cdot |\bar{z}^{n-1} + \cdots + 1| \\ &\leq \max_i \{|a_i|\} \cdot (|\bar{z}|^{n-1} + \cdots + 1) \\ &= \max_i \{|a_i|\} \cdot \frac{|\bar{z}|^n + 1}{|\bar{z}| - 1} \leq \max_i \{|a_i|\} \cdot \frac{|\bar{z}|^n}{|\bar{z}| - 1}. \end{aligned}$$

Thus,  $|\bar{z}|^n \leq \max_i \{|a_i|\} \cdot \frac{|z|^n}{|z|-1}$  which implies that  $|z| - 1 \leq \max_i \{|a_i|\}$ . Thus,  $|z| \leq 1 + \max_i \{|a_i|\}$ .

□

## 2.2 Finite Dimensional Algebras

**Solution:** [⟨ \[CLO05\] Ex. 2.2.1 ⟩](#) :

□

**Solution:** [\[CLO05\] Ex. 2.2.2](#): It is clear that  $\langle p_i(x_i) \rangle \subseteq I \cap k[x_i]$ . Now suppose that  $f(x_i) \in I \cap k[x_i]$ . Then  $\deg(f(x_i))$  must be  $\geq m_i$ . If not, then by the minimality of  $m_i$  we would arrive at a contradiction. Now by the division algorithm, write  $f(x_i) = q(x_i)p_i(x_i) + r(x_i)$  where  $\deg(r_{x_i}) < m_i$ . Then  $r(x_i) = f(x_i) - q(x_i)p_i(x_i) \in I$  and so  $r(x_i)$  must be 0 since if not, we would arrive at a contradiction of the minimality of  $m_i$ .

This gives us an algorithm to compute  $p_i(x_i)$ . Let  $I$  be a zero dimensional ideal and  $G$  a Gröbner basis for  $I$ . Then we know there exists  $m_i$  such that  $\{1, [x_i], \dots, [x_i^{m_i}]\}$  is linearly dependent in  $k[\bar{x}]/I$ . In fact, we may use the Finiteness Theorem to set  $m_i$  to the smallest integer such that  $x_i^{m_i} = \text{LT}(g)$  for some  $g \in G$ . Since  $k[x_1, \dots, x_n]/I$  is a vector space, we can check linear independence in the usual way. See `code/ch2/2_2_2.sage` for a SageMath implementation of this. □

**Solution:** [\[CLO05\] Ex. 2.2.3](#): Let  $0 \neq f(x) \in \sqrt{\langle p(x) \rangle}$ . Then there exists  $m \geq 1$  such that  $f^m \in \langle p(x) \rangle$  and so  $p(x) \mid f(x)^m$ . In particular, each linear factor  $(x - \bar{z})$  of  $p(x)$  divides  $f(x)^m$  and so divides  $f(x)$  as  $(x - \bar{z})$  is irreducible. Thus,  $p_{\text{red}}(x) \mid f(x)$  and so  $f(x) \in \langle p_{\text{red}}(x) \rangle$ . Conversely, suppose  $f(x) \in \langle p_{\text{red}}(x) \rangle$  so that  $\langle p_{\text{red}} \rangle \mid f(x)$ . Label the roots of  $p(x)$  as  $\bar{z}_1, \dots, \bar{z}_r$ , each  $\bar{z}_i \in \bar{k}$ . Then for each  $i$ ,  $(x - \bar{z}_i) \mid f(x)$ . Let  $m_i$  be the multiplicity of  $z_i$  in  $p(x)$  and  $m = \max\{m_1, \dots, m_r\}$ . Then  $p(x) \mid f(x)^m$  and so  $f(x) \in \sqrt{\langle p(x) \rangle}$  □

**Solution:** [\[CLO05\] Ex. 2.2.4](#): We use the algorithm from [\[CLO05\] Ex. 2.2.2](#) implemented in `code/ch2/2_2_2sage`. See `code/ch2/2_2_2sage` for the code in action. □

**Solution:**  $\langle \langle \text{[CLO05] Ex. 2.2.5} \rangle \rangle$  : Then  $\sqrt{I} = I + \langle x(x-1), y(y-2) \rangle$ . Since  $I \subseteq \sqrt{I}$ , we see that  $\dim \mathbb{C}[x, y]/I \geq \dim \mathbb{C}[x, y]/\sqrt{I}$ . A quick SageMath computation confirms this:  $\dim \mathbb{C}[x, y]/I = 9$  and  $\dim \mathbb{C}[x, y]/\sqrt{I} = 2$ . See code/ch2/2\_2\_5.sage for the code in action. Then, since  $I \subseteq \sqrt{I}$  we have that  $V(\sqrt{I}) \subseteq V(I)$ . Notice that

$$y^4x + 3x^3 - y^4 - 3x^2 = y^4(x-1) + 3x^2(x-1) = (y^4 + 3x^2)(x-1)$$

$$x^2y - 2x^2 = x^2(y-2)$$

$$2y^4x - x^3 - 2y^4 + x^2 = 2y^4(x-1) - x^2(x-1) = (2y^4 - x^2)(x-1).$$

Thus,  $(1, 2)$  and  $(0, 0)$  are the only two points in  $V(I)$ . Since it is evident that  $V(\sqrt{I})$  contains these two points, we see in this case that  $V(\sqrt{I}) = V(I)$ .  $\square$

**Solution:** [CLO05] Ex. 2.2.6: A grevlex Gröbner basis for  $I$  is  $\{y^4 - 16y^2, x^3 - x^2, -2x^2\}$ . Thus, by the Finiteness Theorem, we know that for monomials  $x^a y^b$  in  $\mathbb{C}[x, y]/I$  we must have that  $0 \leq a \leq 1$  and  $0 \leq b \leq 3$ . See code/ch2/2\_2\_6.sage for the code in action to compute the table.  $\square$

**Solution:** [CLO05] Ex. 2.2.7: We implement the algorithm described in  $\langle \langle \text{[CLO05] Ex. 1.3.11} \rangle \rangle$ . See /code/ch2/2\_2\_7.sage for the code in action.  $\square$

**Solution:** [CLO05] Ex. 2.2.8:

(a) See code/ch2/2\_2\_8.sage for the code in action.

(b) Since each of the  $I_j$  are maximal ideals and  $I_j \subseteq \sqrt{I_j}$ , we must have that  $I = \sqrt{I_j}$ . Thus  $I(V(I_j)) = I_j$  and we must have that  $I_j = \sqrt{I_j}$ . Since each  $I_j$  is radical and  $I = \bigcap_{j=1}^5 I_j$ , we have by [CLO05] Ex. 2.2.7 that  $I$  is radical.  $\square$

**Solution: [CLO05] Ex. 2.2.9:**

- (a) Let  $f(\bar{x}) \in I + \langle p \rangle$  and let  $1 \leq j \leq d$ . Then  $f(\bar{x}) = g(\bar{x}) + h(\bar{x})p(x_1)$  for some  $g(\bar{x}) \in I$  and  $h(\bar{x}) \in k[\bar{x}]$ . We have that  $(x_1 - a_j) \mid p(x_1)$  and so  $h(\bar{x})p(x_1) \in \langle x_1 - a_j \rangle$ . Thus,  $f(\bar{x}) = g(\bar{x}) + h(\bar{x})p(x_1) \in I + \langle x_1 - a_j \rangle$ . As  $j$  was arbitrary, we have that  $f(\bar{x}) \in \bigcap_j (I + \langle x_1 - a_j \rangle)$ .
- (b) Let  $f(\bar{x}) \in p_j \cdot (I + \langle x_1 - a_j \rangle)$ . Then  $f(\bar{x}) = p_j(x_1) \cdot (g(\bar{x}) + h(\bar{x})(x_1 - a_j))$  for some  $g(\bar{x}) \in I$  and  $h(\bar{x}) \in k[\bar{x}]$ . We have that  $p_j(x_1)g(\bar{x}) \in I$  and  $p_j(x_1)h(\bar{x})(x_1 - a_j) = h(\bar{x})p(x_1) \in \langle p \rangle$ . Thus,  $f(\bar{x}) = p_j(x_1)g(\bar{x}) + h(\bar{x})p(x_1) \in I + \langle p \rangle$ .
- (c) Let  $d = \gcd(p_1, \dots, p_d)$ . Then as  $d \mid p_1$  and  $d \mid p_2$ , we have that  $d \mid \prod_{j \neq 1, 2} (x_1 - a_j)$ . Continuing on inductively, we have that for all  $c \leq d$  that  $d \mid \prod_{j \notin [c]} (x_1 - a_j)$ . In particular, this means that  $d \mid \prod_{j \notin [d]} (x_1 - a_j) = 1$ . Thus,  $d$  itself is a unit in  $k[\bar{x}]$  and  $p_i$  and  $p_j$  are coprime. By Bezout's Lemma, there exists polynomials  $h_1, \dots, h_d \in k[\bar{x}]$  such that  $1 = \sum_{j=1}^d h_j(\bar{x})p_j(x_1)$ .
- (d) Now let  $h(\bar{x}) \in \bigcap_{j=1}^d (I + \langle x_1 - a_j \rangle)$ . As all the  $p_j$  are coprime, we have that there exist polynomials  $h_1, \dots, h_d \in k[\bar{x}]$  such that  $1 = \sum_{j=1}^d h_j(\bar{x})p_j(x_1)$ . Thus,  $h = \sum_{j=1}^d h_j(\bar{x})p_j(x_1)h(\bar{x})$ . Then for all  $1 \leq j \leq d$ , we have that as  $p_j(x_1)h(\bar{x}) \in p_j \cdot (I + \langle x_1 - a_j \rangle) \subseteq I + \langle p \rangle$ . Thus, each summand of  $\sum_{j=1}^d h_j(\bar{x})p_j(x_1)h(\bar{x})$  is in  $I + \langle p \rangle$  and so overall  $h \in I + \langle p \rangle$ .

□

**Solution: [CLO05] Ex. 2.2.10:**

- (a) Let  $\bar{f}^G = \sum_{j=1}^d c_j(f)x^{\alpha(j)}$  and  $\bar{g}^G = \sum_{j=1}^d c_j(g)x^{\alpha(j)}$ . Then by combining like terms, we have that  $\bar{f}^G + \bar{g}^G = \sum_{j=1}^d (c_j(f) + c_j(g))x^{\alpha(j)}$ . On the other hand, we have that  $\overline{f+g}^G = \sum_{j=1}^d c_j(f+g)x^{\alpha(j)}$ . Since  $\bar{f}^G + \bar{g}^G = \overline{f+g}^G$  and each of the  $x^{\alpha(j)}$  are linearly independent, we may equate coefficients and conclude that  $c_j(f) + c_j(g) = c_j(f+g)$ . For  $\lambda \in k$ ,  $\overline{\lambda f}^G = \sum_{j=1}^d c_j(\lambda f)x^{\alpha(j)}$ . Now notice that  $\overline{\lambda f}^G = \lambda \bar{f}^G$  as we are working over a field. Thus, we have by equating coefficients that  $c_j(\lambda f) = \lambda c_j(f)$ . Thus,  $c_j$  is a linear function  $A \rightarrow k$ .
- (b) Let  $\alpha_j \in A^*$  be the linear map  $\alpha_j(f) = c_j(f)$ . Notice that for all  $1 \leq i, j \leq d$  we have that  $\alpha_j(x^{\alpha(i)}) = c_j(x^{\alpha(i)}) = \delta_{i,j}$ . Suppose there exists  $\lambda_1, \dots, \lambda_d \in k$  such that  $\lambda_1 \alpha_1 + \dots + \lambda_d \alpha_d = 0$ . Then for all  $1 \leq i \leq d$  we have that
- $$0 = \left( \sum_{j=1}^d \lambda_j \alpha_j \right) (x^{\alpha(i)}) = \sum_{j=1}^d \lambda_j \alpha_j(x^{\alpha(i)}) = \lambda_i$$
- and so for all  $1 \leq i \leq d$ ,  $\lambda_i = 0$  meaning that  $\{\alpha_1, \dots, \alpha_d\}$  is linearly independent. Since we know that  $d = \dim A = \dim A^*$ , we have that  $\{\alpha_1, \dots, \alpha_d\}$  is a basis for  $A^*$ .
- (c) This was proven in (b).

□

**Solution: [CLO05] Ex. 2.2.11:**

- (a) We want a linear polynomial  $\ell(\bar{x}) = \ell_1 x_1 + \cdots + \ell_n x_n$  takes distinct values at each of the  $p_i \in \mathbb{C}^n$ . Consider the space of all such  $(\ell_1, \dots, \ell_n)$ . This itself is a  $\mathbb{C}$  vector space, call it  $L$ . Let  $L_{i,j}$  be the subspace of  $L$  corresponding to polynomials  $\ell(\bar{x})$  such that  $\ell(p_i) = \ell(p_j)$ . There are finitely many such  $L_{i,j}$ . We know that vector spaces over an infinite field cannot be expressed as the finite union of proper subspaces. Thus,  $L \neq \bigcup_{1 \leq i \neq j \leq m} L_{i,j}$ . This means there exists  $(\ell_1, \dots, \ell_n) \in L \setminus \bigcup_{1 \leq i \neq j \leq m} L_{i,j}$  such that  $\ell(\bar{x}) = \ell_1 x_1 + \cdots + \ell_n x_n$  takes distinct values at each of the  $p_i$ .

**<< Can we do this constructively? >>**

- (b) Let  $\ell(\bar{x})$  be our constructed polynomial from (a). For  $1 \leq i \leq m$ , we define  $g_i \in \mathbb{C}[x_1, \dots, x_n]$  as

$$g_i(\bar{x}) = \frac{\prod_{1 \leq i \neq j \leq m} \ell(\bar{x}) - \ell(\bar{p}_j)}{\prod_{1 \leq i \neq j \leq m} \ell(\bar{p}_i) - \ell(\bar{p}_j)}.$$

Then clearly  $g_i(p_j) = \delta_{ij}$  as desired.

□

**Solution: [CLO05] Ex. 2.2.12:**

- (a) Clearly the map is linear. We now show it is well defined. Let  $[f] = [g] \in \mathbb{C}[\bar{x}]/I$  meaning that  $f - g \in I$ . Thus, we have that

$$\varphi([f]) - \varphi([g]) = \varphi([f - g]) = 0 \implies \varphi([f]) = \varphi([g])$$

as desired.

- (b) Let  $[f], [g] \in \mathbb{C}[\bar{x}]/I$ . Then we have

$$\begin{aligned} \varphi([f] \cdot [g]) &= \varphi([f \cdot g]) \\ &= ((f \cdot g)(p_1), \dots, (f \cdot g)(p_m)) \\ &= (f(p_1) \cdot g(p_1), \dots, f(p_m) \cdot g(p_m)) \\ &= (f(p_1), \dots, f(p_m)) \cdot (g(p_1), \dots, g(p_m)) = \varphi([f]) \cdot \varphi([g]). \end{aligned}$$

Thus,  $\varphi$  is a homomorphism of rings. In fact, it is a homomorphism of  $\mathbb{C}$ -algebras as  $(\lambda \cdot f)(x) := \lambda \cdot f(\bar{x})$  for all  $\lambda \in \mathbb{C}$  and  $f \in \mathbb{C}[\bar{x}]$  and this descends to  $\mathbb{C}[\bar{x}]/I$ .

- (c) We have that  $\varphi$  is surjective and that  $I \subseteq \ker(\varphi)$  as in the proof of [CLO05, Theorem 2.10]. So we want to show that  $\ker(\varphi) \subseteq I$  if and only if  $I = \sqrt{I}$  which holds exactly as in the proof of [CLO05, Theorem 2.10].

□

### 2.3 Gröbner Basis Conversion

**Solution: [CLO05] Ex. 2.3.2:** Recall that *lex* ordering compares the exponents of  $x_1$ , and then in the case of equality compares the exponents of  $x_2$ , and continues on in this manner. As such  $\bar{x}^\alpha = x_1^{\alpha_1} \cdots x_n^{\alpha_n} \geq x_1^a$  if and only if  $\alpha_1 \geq a_1$  which is equivalent to saying that  $x_1^{\alpha_1} \mid x_1^a \mid \bar{x}^\alpha$   $\square$

**Solution: [CLO05] Ex. 2.3.3:**

- (a) Suppose for some  $1 \leq i \leq k$  we have that  $\text{LT}(g_i) \mid x_1^{\alpha_1+1}$ . This would imply that  $\text{LT}(g_i)$  is a power of  $x_1$ . However, we assumed that we were in the situation of the Next Monomial procedure, meaning that the algorithm has not terminated which in turn implies that we have not added any polynomials to  $G_{\text{lex}}$  such that their leading term is a power of  $x_1$ . Thus, no such  $\text{LT}(g_i)$  divides  $x_1^{\alpha_1+1}$ .

(b) Clearly we have that

$$\bar{x}^\beta = x_1^{\alpha_1} \cdots x_{k-1}^{\alpha_{k-1}} x_k^{\alpha_k+1} > x_1^{\alpha_1} \cdots x_{k-1}^{\alpha_{k-1}} x_k^{\alpha_k} = \bar{x}^\alpha.$$

To show that  $\bar{x}^\beta$  is the smallest monomial greater than  $\bar{x}^\alpha$  where no  $\text{LT}(g_i)$  divides  $\bar{x}^\beta$ , we want to show that  $k+1 \leq j, \ell \leq n$  and monomial  $\bar{x}^\gamma$  of the form

$$\bar{x}^\gamma = x_1^{\alpha_1} \cdots x_k^{\alpha_k} x_{k+1}^{c_{k+1}} \cdots x_j^{c_j}, \quad c_{k+1} \geq \alpha_{k+1}, \dots, c_{\ell-1} \geq \alpha_{\ell-1}, c_\ell > \alpha_\ell, c_{\ell+1} \geq 0, \dots, c_j \geq 0. \quad (2.1)$$

sharing the same properties as  $\bar{x}^\beta$ . First, we indeed see that  $\bar{x}^\beta > \bar{x}^\gamma$  as  $\alpha_k + 1 > \alpha_k$  and  $x^\gamma > x^\alpha$  by the assumption on  $\ell$ . We also see that any  $x^\gamma$  such that  $x^\beta > x^\gamma > x^\alpha$  must satisfy Equation (2.1). Suppose towards contradiction that none of the  $\text{LT}(g_i)$  divide  $\bar{x}^\gamma$ . Then we have that

$$\bar{x}^\beta > x_1^{\alpha_1} \cdots x_k^{\alpha_k} x_{k+1}^{c_{k+1}} \cdots x_j^{c_j} \geq x_1^{\alpha_1} \cdots x_k^{\alpha_k} x_{k+1}^{c_{k+1}} \cdots x_\ell^{c_\ell} \geq x_1^{\alpha_1} \cdots x_k^{\alpha_k} x_{k+1}^{c_{k+1}} \cdots x_\ell^{\alpha_\ell+1} > \bar{x}^\alpha.$$

Since No  $\text{LT}(g_i)$  divides  $\bar{x}^\gamma$ , we have that no  $\text{LT}(g_i)$  divides  $x_1^{\alpha_1} \cdots x_k^{\alpha_k} x_{k+1}^{c_{k+1}} \cdots x_\ell^{\alpha_\ell+1}$ . As  $\ell > k$ , this contradicts the maximality of  $k$ . Thus, we cannot have that none of the  $\text{LT}(g_i)$  divide  $\bar{x}^\gamma$ .  $\square$

**Solution: [CLO05] Ex. 2.3.4:** We want to show that  $B_{\text{lex}}$  is a monomial basis for  $k[x_1, \dots, x_n]/I$ . A monomial basis is the set of all monomials that are not in  $\langle \text{LT}(g) \mid g \in G_{\text{lex}} \rangle$ , i.e. the non-leading monomials. However, in the proof of the correctness of the FGLM algorithm, we note that because we are stepping through monomials in  $k[\bar{x}]$  in increasing *lex* order, all non-leading monomials of each  $g \in G_{\text{lex}}$  must have been included in  $B_{\text{lex}}$  already. Thus,  $B_{\text{lex}}$  is our desired monomial basis.  $\square$

**Solution: [CLO05] Ex. 2.3.7:** Since polynomials are added to  $G_{lex}$  with coefficient 1 in the Main Loop (a.), we have that  $G_{lex}$  is a monic Gröbner basis. Then, as monomials are considered in increasing order and we consider them only once per iteration of the Main Loop, we automatically have that  $G_{lex}$  is a *minimal lex* Gröbner basis meaning that for all distinct  $p \in G_{lex}$ , we have that  $LT(p) \notin \langle LT(G_{lex} \setminus \{p\}) \rangle$ . Recall that a *reduced lex* Gröbner basis  $G$  is one such that for all distinct  $p, q \in G$  that no monomial appearing in  $p$  is a multiple of  $LT(q)$ . Suppose there was such distinct  $p, q \in G$  and let  $\bar{x}^\alpha$  be the monomial in  $p$  such that  $LT(q) \mid x^\alpha$ . Then in particular, this implies that  $LT(q) \leq_{lex} \bar{x}^\alpha$ . Suppose that  $LT(q) = \bar{x}^\alpha$ . Then if  $\bar{x}^\alpha$  is not a leading term of some  $p \in G_{lex}$ , then when  $p$  was added to  $G_{lex}$  we must have that  $x^\alpha = LT(q) \in B_{lex}$ , contradicting that  $q \in G_{lex}$ . If  $\bar{x}^\alpha$  is a leading term of some  $p \in G_{lex}$ , then  $p = q$  contradicting distinctness. Now suppose that  $LT(q) <_{lex} \bar{x}^\alpha$ . Then  $LT(q) < LT(p)$ . When  $LT(p)$  was added to  $G_{lex}$ ,  $\bar{x}^\alpha = LT(q)$  was a monomial in  $B_{lex}$  but  $LT(q)$  cannot be an element of  $B_{lex}$ , a contradiction. **<< There should be an easier cleaner solution. >>** □

**Solution: [CLO05] Ex. 2.3.8:** See code/ch2/2\_3\_8.sage for the code in action. □

## 2.4 Solving Equations via Eigenvalues and Eigenvectors

**Solution:** [CLO05] Ex. 2.4.2: If  $f(t)$  and  $g(t)$  are in  $I_M$  so that  $f(M) = g(M) = 0$ , then we have that  $(f+g)(M) = f(M) + g(M) = 0$  so  $(f+g)(t) \in I_M$ . Then if  $p(t) \in k[t]$ , we have that  $(p \cdot f)(M) = p(M) \cdot f(M) = 0$ . Thus,  $I_M$  is an ideal in  $k[t]$ .  $\square$

## 2.5 Real Root Location and Isolation

# Chapter 3

## Resultants

### 3.1 The Resultant of Two Polynomials

**Solution:** [CLO05] Ex. 3.1.1: Swapping two adjacent columns in a matrix multiplies the determinant by  $-1$ . Since the matrix for  $\text{Res}(g, f)$  is formed by moving each of the  $l$  columns of  $\text{Res}(f, g)$  corresponding to  $g$  a total of  $m$  columns each, we have that the determinants must differ by a factor of  $(-1)^{lm}$ .  $\square$

**Solution:** [CLO05] Ex. 3.1.3:

(a) Let  $f(x) = a_0(x - \xi_1) \cdots (x - \xi_l)$  and  $g(x) = b_0(x - \eta_1) \cdots (x - \eta_m)$ . To see the first equality, we have that

$$a_0^m b_0^l \prod_{i=1}^l \prod_{j=1}^m (\xi_i - \eta_j) = a_0^m \prod_{i=1}^l b_0 (\xi_i - \eta_1) \cdots (\xi_i - \eta_m) = a_0^m \prod_{i=1}^l g(\xi_i).$$

The equality  $a_0^m b_0^l \prod_{i=1}^l \prod_{j=1}^m (\xi_i - \eta_j) = (-1)^{lm} b_0^l \prod_{j=1}^m f(\eta_j)$  follows the same logic using the fact that  $(\xi_i - \eta_j) = -(\eta_j - \xi_i)$  and there are  $lm$  many such pairs.

(b) Let  $f_1(x) = a_1(x - \xi_1) \cdots (x - \xi_{l_1})$ ,  $f_2(x) = a_2(x - \xi_{l_1+1}) \cdots (x - \xi_{l_2})$ , and  $g(x) = b_0(x - \eta_1) \cdots (x - \eta_m)$ .

Then  $f_1(x)f_2(x) = a_1a_2(x - \xi_1) \cdots (x - \xi_{l_1})(x - \xi_{l_1+1}) \cdots (x - \xi_{l_2})$ . Thus, we have that

$$\begin{aligned} \text{Res}(f_1f_2, g) &= a_1^m a_2^m b_0^{l_1+l_2} \prod_{i=1}^{l_1+l_2} \prod_{j=1}^m (\xi_i - \eta_j) \\ &= a_1^m a_2^m b_0^{l_1+l_2} \left( \prod_{i=1}^{l_1} \prod_{j=1}^m (\xi_i - \eta_j) \right) \left( \prod_{i=l_1+1}^{l_2} \prod_{j=1}^m (\xi_i - \eta_j) \right) \\ &= \left( a_1^m b_0^{l_1} \prod_{i=1}^{l_1} \prod_{j=1}^m (\xi_i - \eta_j) \right) \left( a_2^m b_0^{l_2} \prod_{i=l_1+1}^{l_2} \prod_{j=1}^m (\xi_i - \eta_j) \right) = \text{Res}(f_1, g) \cdot \text{Res}(f_2, g). \end{aligned}$$

$\square$

**Solution:** [CLO05] Ex. 3.1.4: The result is seen by looking at the definition of  $\text{Res}(F, G)$  for homogeneous  $F, G \in k[x, y]$ . We see that  $a_0 = 1$ , the coefficient of  $x^l$ , lies on the first  $m$  entries of the main diagonal and that  $b_m = 1$ , the coefficient of  $y^m$ , lies on the last  $l$  entries of the main diagonal. All other entries of the matrix are 0 and so the resulting matrix is just the  $(l + m) \times (l + m)$  identity matrix which has determinant 1.  $\square$

**Solution:** [CLO05] Ex. 3.1.7:  $\langle \langle$  This is clear to see if you write out the matrix but awful to type out formally...  $\rangle \rangle$   $\square$

**Solution:** [CLO05] Ex. 3.1.8:

(a) Since  $m = \deg(g) = 0$ , there are no columns with the coefficients of  $f$ . Thus,  $\text{Syl}(f, g)$  is a  $l \times l$  matrix just consisting of  $b_0$  along the main diagonal and so  $\text{Res}(f, g) = b_0^l$ .

$\square$

## Chapter 4

# Computation in Local Rings

### 4.1 Local Rings

**Solution:** [CLO05] Ex. 4.1.6: Let  $R$  be the set of all elements  $x$  of  $F$  such that  $v(x) \geq 0$ , along with 0.

- (a) We claim that the unique maximal ideal in  $R$  is  $M := \{x \in R \mid v(x) > 0\}$ . To show this, we will show that every element in  $R \setminus M$ , the nonzero elements  $x$  such that  $v(x) = 0$ , is a unit in  $R$ . As such, let  $0 \neq x \in R \setminus M$ . Then  $0 \neq x \in F$  implies that  $0 \neq x^{-1} \in F$ . We claim that  $x^{-1} \in R \setminus M$ . Indeed, we have that

$$v(1) + v(x^{-1}) = v(1 \cdot x^{-1}) = v(x^{-1}) = v(x) + v(x^{-1}) = v(xx^{-1}) = v(1)$$

and so  $v(x^{-1}) = 0$  as well showing that  $x^{-1} \in R \setminus M$ . Thus,  $R$  is a local ring.

- (b) The check that  $v$  is a discrete valuation is straightforward **<< and omitted for now >>**. The maximal ideal is given by

$$M = \{x \in k(x) \mid v(x) = 0\} = \left\{ \frac{n}{d} \in k(x) \mid f \text{ does not divide } n, d \right\}.$$

- (c) The check that  $v$  is a discrete valuation is straightforward **<< and omitted for now >>**. The maximal ideal is given by

$$M = \{x \in \mathbb{Q} \mid v(x) = 0\} = \left\{ \frac{n}{d} \in \mathbb{Q} \mid p \text{ does not divide } n, d \right\}.$$

□

**Solution: [CLO05] Ex. 4.1.7:**

(a) Let  $c_0(x) = 1$ . Treating  $a_{i,1}$  as an indeterminate, we have that

$$\begin{aligned}
 f(x, a_i + a_{i,1}x) &\equiv \sum_{j=0}^n c_{n-j}(x)(a_i + a_{i,1}x)^j \\
 &\equiv \sum_{j=0}^n c_{n-j}(x) \sum_{\ell=0}^j \binom{j}{\ell} (a_{i,1}x)^\ell a_i^{j-\ell} \\
 &\equiv \sum_{j=0}^n c_{n-j}(x)(a_i^j + ja_{i,1}xa_i^{j-1}) \\
 &\equiv f(x, a_i) + (a_{i,1}x) \frac{\partial f}{\partial y}(x, a_i) \equiv f(0, a_i) + \left( C + \frac{\partial f}{\partial y}(0, a_i)a_{i,1} \right) x \pmod{x^2}
 \end{aligned}$$

where  $C$  is some polynomial expression in the coefficients of  $f$  and  $a_i$ , and in particular doesn't depend on  $a_{i,1}$  or  $x$ . Such  $C$  exists as all terms with  $\deg_x \geq 2$  go to  $0 \pmod{x^2}$  and we can factor out the remaining  $x$ . Then as  $f(0, a_i) = 0$ , we want  $a_{i,1}$  such that  $\left( C + \frac{\partial f}{\partial y}(0, a_i)a_{i,1} \right) x \equiv 0 \pmod{x^2}$ . This is equivalent to saying that  $C + \frac{\partial f}{\partial y}(0, a_i)a_{i,1} = 0$  in  $k$ . Then as  $a_i$  is a *simple* root, we know that  $\frac{\partial f}{\partial y}(0, a_i) \neq 0$  and so we can solve for  $a_{i,1}$ .

(b) Let  $c_0(x) = 1$  and  $\ell \geq 1$ . As  $f(x, y_i^{(\ell)}(x)) \equiv 0 \pmod{x^{\ell+1}}$ , let  $C$  be a constant which is a polynomial in the coefficients of  $f$  and coefficients of  $y_i^{(\ell)}$  such that  $f(x, y_i^{(\ell)}(x)) \equiv Cx^{\ell+1} \pmod{x^{\ell+2}}$ . Treating  $a_{i,\ell+1}$  as an indeterminate, we have by similar arguments to above that

$$\begin{aligned}
 f(x, y_i^{(\ell+1)}(x)) &\equiv f(x, y_i^{(\ell)}(x)) + (a_{i,\ell+1}x^{\ell+1}) \frac{\partial f}{\partial y}(x, y_i^{(\ell)}(x)) \\
 &\equiv f(x, y_i^{(\ell)}(x)) + (a_{i,\ell+1}x^{\ell+1}) \frac{\partial f}{\partial y}(0, a_i) \equiv \left( D + a_{i,\ell+1} \frac{\partial f}{\partial y}(0, a_i) \right) x^{\ell+1} \pmod{x^{\ell+2}}.
 \end{aligned}$$

This **<< implies >>** that  $D + a_{i,\ell+1} \frac{\partial f}{\partial y}(0, a_i) = 0$  in  $k$ . Again, as  $a_i$  is a simple root, we know that  $\frac{\partial f}{\partial y}(0, a_i) \neq 0$  and so we can solve for  $a_{i,\ell+1}$ .

(c) The prior two parts lay out an inductive argument for the claim. □

**Solution: [CLO05] Ex. 4.1.11:** Note that  $M = \langle x_1, \dots, x_n \rangle$  is a prime, in fact maximal, ideal in  $k[x_1, \dots, x_n]$ . Thus, every ideal  $I_M \trianglelefteq R$  is of the form  $I_M = \left\{ \frac{a}{s} \mid a \in I, s \notin M \right\}$  for some ideal  $I \trianglelefteq k[x_1, \dots, x_n]$ . We know that  $I$  is generated by polynomials  $\{f_1, \dots, f_s\} \subseteq k[x_1, \dots, x_n]$ . Then, every element of the form  $\frac{1}{s}$  for  $s \notin M$  is an element of  $R_p$ . These two facts yields that  $\{f_1, \dots, f_s\}$  generates  $I_M$  in  $R$ . □

## 4.2 Multiplicities and Milnor Numbers

**Solution:** [CLO05] Ex. 4.2.1:

- (a) Recall that the maximal ideal of  $k[x_1, \dots, x_n]_{\langle x_1 - a_1, \dots, x_n - a_n \rangle}$  is the set  $\left\{ \frac{f}{g} \mid f, g \in k[x_1, \dots, x_n], g(\bar{a}) \neq 0, f(\bar{a}) = 0 \right\}$ . Thus, as  $1 + 0 = 1 \neq 0$ , we know that  $1 + x$  is not in the maximal ideal  $\mathfrak{m}$  of  $R$  and so must be a unit.
- (b) This follows immediately from part **a**. where  $1 + x$  is a unit in  $R$  and the fact that  $x^2 + x^3 = x^2(1 + x)$ .
- (c) Note that for all  $h \in \langle x, y \rangle \subseteq R$ ,  $1 + h(0, 0) \neq 0$  and so  $\frac{1}{1+h} \in R$ . Then,  $\langle x, y \rangle \subseteq k[x, y]$  is the set of all polynomials with constant term 0. Since we know that elements  $f = \frac{g}{b} \in R$ , where  $g, b \in k[x, y]$ , are such that  $b(0, 0) \neq 0$ , we know there is a non-zero constant term. Via rescaling, we may assume that  $b$  has constant term 1 and so  $b = 1 + h$  for some  $h \in \langle x, y \rangle \subseteq k[x, y]$ . To see uniqueness, suppose  $\frac{g'}{1+h'} = f = \frac{g}{1+h}$  so that there exists  $s \in k[x, y] \setminus \langle x, y \rangle$  such that

$$0 = s(g'(1+h) - g(1+h')) = s(g' - g + g'h - gh').$$

We know that  $s \neq 0$  and so  $g'(1+h) = g(1+h')$ . Thus,  $\frac{g}{1+h} = \frac{g'}{1+h'}$  in  $k[x, y]$ . The constant term being 1 in each denominator immediately implies uniqueness.

- (d) Let  $f \in R$  and  $g, h$  as in (c) such that  $f = \frac{g}{1+h}$ . Note that  $g(1-h+h^2) \in R$  by the inclusion  $k[x, y] \hookrightarrow R$ . We want to show that  $f - g(1-h+h^2) \in \langle x^2, y^2 \rangle \subseteq R$ . To see this, first we compute the following:

$$f - g(1-h+h^2) = \frac{g}{1+h} - g(1-h+h^2) = \frac{-h^3}{1+h}.$$

As  $h \in \langle x, y \rangle$ , we have that  $h = ax + by$  for some  $a, b \in R$ . Then,  $h^3$  is such that every term has degree at least 2 in  $x$  or  $y$  and so  $\frac{-h^3}{1+h} \in \langle x^2, y^2 \rangle$  as desired.

- (e) Since we are working in  $R/\langle x^2, y^2R \rangle$ , in  $g$  and  $h$  we may ignore terms in  $f, g$  which have degree at least 2 in either  $x$  or  $y$ . Writing  $g = g_1 + g_x x + g_y y + g_{xy} xy$  where  $g_1, g_x, g_y$ , and  $g_{xy} \in k$ , and similarly  $h = h_x x + h_y y + h_{xy} xy$ , and expanding  $[f] = [g(1-h+h^2)]$  yields the desired constants. Uniqueness follows from the uniqueness of  $f, g$ .

□

**Solution:** [CLO05] Ex. 4.2.3:

(a) Using SageMath, we find the following four solutions:

$$(-3.464102, -1.732051)$$

$$(3.464102, 1.732051)$$

$$(-1.732051, 1.732051)$$

$$(1.732051, -1.732051)$$

(b) In Figure 4.1, we see that two points of intersection “bounce” which we know geometrically indicates these points have multiplicity  $> 1$ .

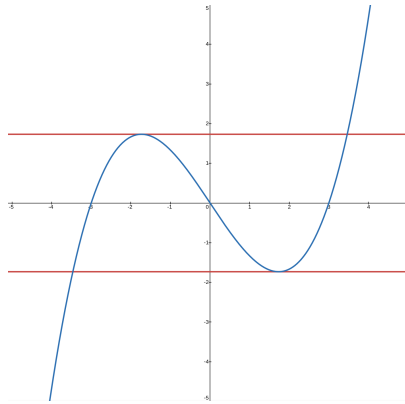

Figure 4.1: Real Plot of  $y^2 - 3 = 0, 6y - x^3 + 9x = 0$ .

(c) Using SageMath, we see that a monomial basis of  $k[x, y]/I$  is given by  $\{1, x, y, x^2, xy, x^2y\}$ . Using this basis,  $m_x$  has the following matrix

$$\begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 18 \\ 1 & 0 & 0 & 9 & 0 & 0 \\ 0 & 0 & 0 & 6 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 9 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{pmatrix}$$

which has characteristic polynomial

$$u^6 - 18u^4 + 81u^2 - 108 = (u^2 - 12)(u^2 - 3)^2.$$

(d) Further factoring of the characteristic polynomial over  $k$  into linear parts yields that

$$u^6 - 18u^4 + 81u^2 - 108 = (u^2 - 12)(u^2 - 3)^2 = (u - 2\sqrt{3})(u + 2\sqrt{3})(u - \sqrt{3})^2(u + \sqrt{3})^2.$$

Applying [CLO05, §4.2, Proposition 2.7] yields that the points with  $x$ -coordinate  $\pm\sqrt{3}$  each have multiplicity 2, as expected from Figure 4.1, and the other points with  $x$ -coordinate  $\pm 2\sqrt{3}$  each have multiplicity 2.

(e) **<< TODO: Return once you have learned more about resultants. >>**

□

**Solution : [CLO05] Ex. 4.2.6:** To show that  $k[\bar{x}]_M/Ik[\bar{x}]_M$  is a local ring, it suffices to show that  $(k[\bar{x}]/Ik[\bar{x}])_M \simeq k[\bar{x}]_M/Ik[\bar{x}]_M$ . Consider the following morphism:

$$\begin{aligned} \phi : k[\bar{x}]_M/Ik[\bar{x}]_M &\rightarrow (k[\bar{x}]/Ik[\bar{x}])_M \\ \frac{f}{g} + Ik[\bar{x}]_M &\mapsto \frac{f + I}{g + I}. \end{aligned}$$

It is immediate that  $\phi$  is well defined and surjective. To see that  $\phi$  is injective, suppose that  $\frac{f}{g} + Ik[\bar{x}]_M \in \ker \phi$ . Then  $\frac{f+I}{g+I} = 0$  implies that  $f \in I$ . Thus,  $f \in Ik[\bar{x}]_M$  which implies that  $\frac{f}{g} + Ik[\bar{x}]_M = 0$ . Thus,  $\phi$  is an isomorphism which implies that  $k[\bar{x}]_M/Ik[\bar{x}]_M$  is a local ring.

To see that  $k[\bar{x}]_M/Ik[\bar{x}]_M$  has dimension  $\geq 1$  as a  $k$ -vector-space, we show that evaluation at  $p$ ,  $\text{ev}_p$  is a well-defined linear surjection of vector spaces. It is immediate that  $\text{ev}_p$  is a linear map. To see that it is well defined, suppose  $\frac{f}{g} + Ik[\bar{x}]_M = \frac{f'}{g'} + Ik[\bar{x}]_M$ . Then we have that  $\frac{fg' - f'g}{gg'} \in Ik[\bar{x}]_M$  which implies that  $fg' - f'g \in K$ . Thus,  $\text{ev}_p\left(\frac{f}{g} - \frac{f'}{g'} + Ik[\bar{x}]_M\right) = 0$  and so by linearity of  $\text{ev}_p$ , we have that  $\text{ev}_p\left(\frac{f}{g} + Ik[\bar{x}]_M\right) = \text{ev}_p\left(\frac{f'}{g'} + Ik[\bar{x}]_M\right)$  as desired. Since  $\text{ev}_p$  is obviously surjective, we must have that  $\dim_k k[\bar{x}]_M/Ik[\bar{x}]_M \geq 1$ . □

**Solution : [CLO05] Ex. 4.2.7:** As  $\bigcap_{i=1}^n M_i$  is an ideal, it is finitely generated by polynomials  $\{f_1, \dots, f_s\}$ . For each  $f_j \in \bigcap_{i=1}^n M_i$ , we have that for all  $1 \leq i \leq n$  that  $f_j(p_i) = 0$ . Thus,  $f_j \in \mathbf{I}(\mathbf{V}(I)) = \sqrt{I}$  and so there exists  $d_j > 0$  such that  $f_j^{d_j} \in I$ . Let  $d = \sum_{j=1}^s d_j$ . Then for all  $f \in \bigcap_{i=1}^n M_i$ , we have that  $f^d \in I$  and so  $(\bigcap_{i=1}^n M_i)^d \subseteq I$ . □

**Solution : [CLO05] Ex. 4.2.9:** Fix  $1 \leq i \leq n$ . As  $\sum_{j=1}^m e_j \equiv 1 \pmod{I}$  and for  $i \neq j$  we have that  $e_i e_j \equiv 0 \pmod{I}$ , we have that

$$e_i \equiv e_i \sum_{j=1}^m e_j = e_i^2 + \sum_{\substack{j=1 \\ j \neq i}}^m e_i e_j \equiv e_i^2 \pmod{I}.$$

□

**Solution: [CLO05] Ex. 4.2.11:**

- (a) If  $f \in I$ , then  $f(p_i) = 0$  and so  $[f]_i = [0]_i$  in  $A_i$  meaning  $f \in Q_i$ . To see the desired description of  $Q_i$ , we have that

$$\begin{aligned} f \in Q_i &\iff [f]_i = [0]_i \\ &\iff f \in I\mathcal{O}_i \\ &\iff f = \frac{g_i}{u}, u \in k[\bar{x}] \setminus M_i, g_i \in I \iff f \cdot u = g_i \in I. \end{aligned}$$

- (b) Fix  $1 \leq i \leq m$  and  $j \neq i$ . Let  $\tilde{u} := 1 - g_j$ . We have that  $\tilde{u} \notin M_i$ . For  $k \neq j$  we have that  $(\tilde{u} \cdot g_j)(p_k) = \tilde{u}(p_k) \cdot g_j(p_k) = 1 \cdot 0 = 0$ . On the other hand, we have that  $(\tilde{u} \cdot g_j)(p_j) = \tilde{u}(p_j) \cdot g_j(p_j) = 0 \cdot 1 = 0$ . Thus,  $\tilde{u} \cdot g_j \in \mathbf{I}(\mathbf{V}(I)) = \sqrt{I}$  and so there exists  $d$  such that  $(\tilde{u} \cdot g_j)^d \in I$ . Let  $u = \tilde{u}^d$ . Then  $u \notin M_i \implies \tilde{u} \notin M_i$  and yet  $u \cdot g_j^d \in I$ . Thus, by (a) we have that  $g_j^d \in Q_i$ .
- (c) Since  $I \subseteq Q_i$ , we have that  $\mathbf{V}(Q_i) \subseteq \{p_1, \dots, p_m\}$  and so we can consider this finite list of points individually. For all  $j \neq i$ , there exists  $d_j$  such that  $g_j^{d_j} \in Q_i$ . Since  $g_j^{d_j}(p_j) = 1$ , we have that  $p_j \notin Q_i$ . For  $f \in Q_i$ , there exists  $u \notin M_i$  such that  $u \cdot f \in I$ . Since  $u(p_i) \neq 0$  but  $u(p_i) \cdot f(p_i) = 0$ , we must have that  $f(p_i) = 0$ . Thus,  $\mathbf{V}(Q_i) = \{p_i\}$ . With this,  $\sqrt{Q_i} = \mathbf{I}(\mathbf{V}(Q_i)) = \mathbf{I}(\{p_i\}) = M_i$  as desired.
- (d) Suppose that  $f \cdot g \in Q_i$ . If  $f \in Q_i$  we are done, so suppose not. Then  $f(p_i) \neq 0$  but  $f(p_i) \cdot g(p_i) = 0$  which implies that  $g(p_i) = 0$ . Thus,  $g \in M_i = \sqrt{Q_i}$  and so there exists  $d > 0$  such that  $g^d \in M_i$ . **⟨⟨ Unsure about the relevance of the hint saying that  $A_i$  is a local ring. ⟩⟩**
- (e) By (a), we have that  $I \subseteq Q_i$  for all  $i$  and so  $I \subseteq Q_1 \cap \dots \cap Q_m$ . Now suppose that  $f \in Q_1 \cap \dots \cap Q_m$  which implies that for all  $i$ ,  $f \in \ker \varphi_i$ . By the proof of [CLO05, §4.2, Theorem 2.2], this means that  $f \in I$ . Thus,  $I = Q_1 \cap \dots \cap Q_m$ .
- (f) We know that  $\varphi: k[\bar{x}] \rightarrow A_1 \times \dots \times A_m$  is surjective. Trivially, the projection  $\pi_i: A_1 \times \dots \times A_m \rightarrow A_i$  is also surjective. Thus,  $\varphi_i = \pi_i \circ \varphi$  is surjective. By an isomorphism theorem, this means that  $k[\bar{x}]/Q_i \simeq A_i$ .

□

**Solution: [CLO05] Ex. 4.2.12:**

- (a) As  $f(p_i)$  is the only eigenvalue of  $m_f: A_i \rightarrow A_i$  and every vector space is the direct sum of generalized eigenspaces for each eigenvalue of a linear map, we must have that  $A_i$  is the only generalized eigenspace for  $m_f$ .
- (b) By [CLO05, §2.4, Theorem 4.5], the values of  $f$  on  $\mathbf{V}(I) = \{p_1, \dots, p_m\}$  are all eigenvalues of  $f$ . The result is immediate by the uniqueness of the set of eigenvalues of a function and the consequent uniqueness of direct sum decomposition of  $A$  into generalized eigenspaces.

□

**Solution:** [CLO05] Ex. 4.2.14:      << **TODO: Come back after learning more about resultants.** >>      □

**Solution:** [CLO05] Ex. 4.2.15:

- (a) Let  $I = \mathbf{I}(\ell_1, \dots, \ell_n)$ . Since  $\mathbf{V}(\ell_1, \dots, \ell_n) = \{\bar{0}\}$ , we must have that the matrix with rows given by the coefficients of the  $\ell_i$  is full rank. Thus,  $k[\bar{x}]/I \simeq k$ . Let  $f = 1$  so that  $m_f$  is the  $1 \times 1$  identity matrix. Then  $(-1)^1(u-1)^{m(\bar{0})} = \det(m_f - uI) = 1 - u$  which implies that  $m(\bar{0}) = 1$  as desired.
- (b) By [CLO05, §4.2, Proposition 2.11], we have that the multiplicity of the origin in  $\mathbf{V}(I)$  is also given by  $\dim_k k[[\bar{x}]]/Ik[[\bar{x}]]$ . Since the Jacobian matrix is invertible, << **there is** >> an automorphism of  $k[[\bar{x}]]$  sending  $f_i$  to  $x_i$ . Since  $\bar{0} \in \mathbf{V}(x_1, \dots, x_n)$  which is a variety defined by homogeneous linear polynomials, by (a) we have that the multiplicity of the origin is 1.

**Remark:** Supposedly, one way to see this is via Nakayama's Lemma. From the [Wikipedia page stating an application to local rings](#), we see that Nakayama's Lemma tells us that generators of the cotangent space  $\mathfrak{m}/\mathfrak{m}^2$  lift to generators of  $\mathfrak{m}$  for any maximal ideal  $\mathfrak{m}$ .

□

**Solution:** [CLO05] Ex. 4.2.16:      Let  $f \in k[\bar{x}]$  be such that  $f$  has an ordinary double point at the origin. By [CLO05, §4.2, Proposition 2.11], the Milnor number of 0 is given by the multiplicity of 0 of  $\left\langle \frac{\partial f}{\partial x_1}, \dots, \frac{\partial f}{\partial x_n} \right\rangle$ . Letting  $g_i := \frac{\partial f}{\partial x_i}$ , the Jacobian of  $g_1, \dots, g_n$  is the invertible matrix of second-order partial derivatives. By ??, we know this value is 1. Thus, the Milnor number of an ordinary double point is 1.      □

### 4.3 Term Orders and Division in Local Rings

**Solution:** [CLO05] Ex. 4.3.8:

- (a) Following the given hint, let  $>_r$  be the reverse ordering of  $>$ . Then by [CLO15, §2.4, Corollary 6], to prove that  $>_r$  is a well-ordering it suffices to show that  $\alpha \geq_r 0$  for all  $\alpha \in \mathbb{Z}_{\geq 0}^n$ . Since for all  $i$  we have that  $1 > x_i$ , we have that  $x_i >_r 1$ . Compatibility with multiplication then inductively shows that for all  $\alpha \in \mathbb{Z}_{\geq 0}^n$  that  $\alpha \geq_r 0$  and this  $>_r$  is a well-ordering. Translating back to  $>$ , this shows that every nonempty set of monomials has a maximal element.
- (b) Since every nonempty set of monomials has a maximal element by (a), we can define multideg, LT, and LC in the usual manner.
- (c) **<< Immediate >>**
- (d) **<< Immediate >>**

□

**Solution:** [CLO05] Ex. 4.3.9: Clearly if the remainder is 0, then the result of the normal form algorithm gives a certificate of ideal membership. However, the converse is not necessarily true as seen when dealing with division by sets that do not necessarily form a Gröbner (or as seen later, standard) basis. **<< TODO: Example >>**

□

**Solution:** [CLO05] Ex. 4.3.10: In the proof of correctness, we found polynomials  $A_{l,j}$ ,  $U_j$ , and  $H_j$  such that on the  $j^{\text{th}}$  pass through the WHILE loop we had

$$U_j F = A_{1,j} F_1 + \cdots + A_{s,j} F_s + H_j.$$

For  $j = 0$ , we can take  $H_0 = F$ ,  $U_0 = 1$ , and  $A_{l,0} = 0$  for all  $l$ . The proof of correctness of [CLO05, §4.2, Theorem 3.10], there are given rules on how to update not just  $H_j$  and  $U_j$  but also how to find  $A_{l,j+1}$  from  $A_{l,j}$  depending on what  $G$  is on each given loop.

□

**Solution:** [CLO05] Ex. 4.3.13: **<< Is there a non-tedious non-inductive way to do this? >>**

□

**Solution:** [CLO05] Ex. 4.3.14: Homogenize  $f, f_1, \dots, f_s$  to obtain  $F, F_1, \dots, F_s$ . Then run the algorithm described in [CLO05, §4.2, Theorem 3.10]. Dehomogenize the result by setting  $t = 1$ . We know that homogenization and dehomogenization preserve leading terms and both take units to units. This proves [CLO05, §4.2, Corollary 3.13]. **<< TODO: SageMath implementation. >>**

□

## 4.4 Standard Bases in Local Rings

Solution: [CLO05] Ex. 4.4.1:

- (a) Recall that every semigroup order  $>$  on  $R$  can be lifted to a monomial order  $>'$  on  $k[t, \bar{x}]$  such that homogenization and dehomogenization with respect to  $t$  maintains leading terms. Thus, we can consider  $\langle \text{LT}(I) \rangle \subseteq k[t, \bar{x}]$  with respect to  $>'$ . Here, as we are dealing with a monomial order, Dickson's Lemma implies that  $\langle \text{LT}(I) \rangle$  has a finite generating set. As dehomogenization, by setting  $t = 1$ , takes leading terms to leading terms, we have that  $\langle \text{LT}(I) \rangle \subseteq R$  has a finite generating set.

- (b) **<< Immediate >>**

□

Solution: [CLO05] Ex. 4.4.2:

- (a) Clearly if the remainder of  $f$  on division by  $G$  is 0 and  $\langle G \rangle = I$  then  $f \in I$ . Now suppose that  $f \in I$ . Then  $f = f + 0$  and the uniqueness of the remainder as shown in [CLO05, §4.4, Theorem 4.3] shows that the remainder upon division by  $G$  is 0.

- (b) We saw in [CLO05] Ex. 4.4.1 that every local ring  $R$  has a standard basis which is finite. **<< Unsure where the above part is used. >>**

- (c) **<< Trivial >>**

□

Solution: [CLO05] Ex. 4.4.3: **<< TODO >>**

□

Solution: [CLO05] Ex. 4.4.4: **<< TODO >>**

□

Solution: [CLO05] Ex. 4.4.6: The algorithm is basically the one given in the proof of  $c \implies a$  in the proof of [CLO05, §4.4, Theorem 4.3]. **<< TODO: SageMath implementation. >>**

□

## 4.5 Applications of Standard Bases

**Solution:** [CLO05] Ex. 4.5.2:

- (a) As  $f_1, \dots, f_n$  are homogeneous already, homogenization with respect to  $x_0$  does nothing. Thus, as  $V(f_1, \dots, f_n) = \{\bar{0}\}$ , they have no non-trivial solutions when  $x_0 = 0$ . Given this, Bézout's Theorem [CLO05, §3.5, Theorem 5.5] applies. Combining Bézout's Theorem with [CLO05, §4.2, Theorem 2.5] yields that  $d_1 \cdots d_n = \dim k[\bar{x}]/I = m(\bar{0})$ .
- (b) Apply (a) to  $\left\langle \frac{\partial f}{\partial x_1}, \dots, \frac{\partial f}{\partial x_n} \right\rangle$ .

□

**Solution:** [CLO05] Ex. 4.5.3:      **<< TODO after installing Singular >>**

□

**Solution:** [CLO05] Ex. 4.5.4:      **<< TODO after installing Singular >>**

□

**Solution:** [CLO05] Ex. 4.5.5:

- (a) Trivial.
- (b) We take ideas from [MPT89, Proposition 4]. Recall that degree-anticompatible orderings are local orderings. Then for all  $h = \frac{f}{1+g} \in k[\bar{x}]_{(x_1, \dots, x_n)}$  we have that  $\text{LT}(h) = \text{LT}(f) = \text{LT}(f_{\min}) = \text{LT}(h_{\min})$ . Let  $\text{in}(I) = \langle f_{\min} \mid f \in I \rangle$ . Let  $G = \{g_1, \dots, g_t\}$ . By similar arguments to (a), we have that

$$\langle \text{LT}(\text{in}(I)) \rangle = \langle \text{LT}(I) \rangle = \langle \text{LT}(G) \rangle = \langle \text{LT}(\text{in}(G)) \rangle.$$

Thus,  $\text{in}(G)$  is a standard basis for  $I$  and so  $\mathbf{C}(V) = \mathbf{V}(\text{in}(G))$ .

**Remark:** In fact, we have shown more. We know that  $G = \{g_1, \dots, g_t\}$  are all polynomials and so it makes sense to talk about Gröbner bases. Let  $>$  be the degree-anticompatible ordering in question and define  $>_w$  by undoing the degree-anticompatibility in that

$$\bar{x}^\alpha >_w \bar{x}^\beta \iff |\alpha| > |\beta| \text{ or } |\alpha| = |\beta| \text{ and } \bar{x}^\alpha > \bar{x}^\beta.$$

Then we can actually show that  $G$  is a Gröbner basis with respect to  $>_w$ .

- (c) **<< TODO after installing Singular >>**

□

# Chapter 5

## Modules

### 5.1 Modules over Rings

⟨⟨ TODO: Every exercise as qualifying prep. ⟩⟩

Solution: [CLO05] Ex. 5.1.2:

- (a) Clearly  $f_1, f_2, f_3 \in \ker A$  and so  $M \subseteq \ker A$ . Now suppose that  $f = \begin{pmatrix} p & q & r \end{pmatrix}^\top \in R^3$  such that  $Af = 0$ . Thus,  $xp + yq + zr = 0$ . As  $k[x, y, z] = k[x, y][z]$ , there exists  $p_1, q_1 \in k[x, y]$  and  $p_2, q_2 \in k[x, y, z]$  such that  $p = p_1 + zp_2$  and  $q = q_1 + zq_2$ . Let  $z = 0$ . Then  $0 = xp_1 + yq_1$  and so there exists  $a \in k[x, y]$  such that  $xa = q_1$  and so  $-ya = p_1$ . Given this, we have that

$$\begin{pmatrix} p \\ q \\ r \end{pmatrix} = -af_1 + \begin{pmatrix} zp_2 \\ zq_2 \\ r \end{pmatrix}.$$

As both  $\begin{pmatrix} p & q & r \end{pmatrix}^\top$  and  $-af_1$  are in  $\ker A$ , we have that  $\begin{pmatrix} zp_2 & zq_2 & r \end{pmatrix}^\top$  is in  $\ker A$ . Thus,  $xzp_2 + yzq_2 + zr = 0$  and so  $r = -xp_2 - yq_2$  and overall we have that

$$\begin{pmatrix} p \\ q \\ r \end{pmatrix} = -af_1 + \begin{pmatrix} zp_2 \\ zq_2 \\ r \end{pmatrix} = -af_1 + p_2f_2 + q_2f_3 \in M.$$

- (b) Consider  $\langle f_1, f_2 \rangle$ . Then for all  $a, b \in k[x, y]$  we have that  $af_1 + bf_2 = \begin{pmatrix} ay + bz & -ax & -bx \end{pmatrix}^\top$ . Thus, for all  $\begin{pmatrix} p & q & r \end{pmatrix}^\top \in \langle f_1, f_2 \rangle$  we must have that  $x \mid q$  and  $x \mid r$ . However, we know that  $f_3 = \begin{pmatrix} 0 & z & -y \end{pmatrix}^\top \in M$  but  $x \nmid z$  and  $x \nmid -y$ . Thus,  $\langle f_1, f_2 \rangle \subsetneq M$ . The other cases are similar.

- (c) We have that  $-zf_1 + yf_2 - xf_3 = \bar{0}$ .
- (d) Nothing to do.
- (e) We pass to  $F = \text{Frac}(R)$ . Here we see that  $M$  has dimension  $\leq 2$  as a  $F$  vector space by (c). Clearing denominators of any  $F$ -linear dependence yields an  $R$ -linear dependence of 3 vectors and so there is no linearly independent set with 3 vectors. **<< TODO: brutal calculation >>**

□

**Solution: [CLO05] Ex. 5.1.8:**

- (a) Let  $\phi : M \rightarrow R$  be a  $R$ -module homomorphism such that  $\phi(x^2) = y$  and  $\phi(y^3) = x$ . Then we must have that

$$0 = \phi(0) = \phi(y^3x^2 - x^2y^3) = y^3\phi(x^2) - x^2\phi(y^3) = y^4 - x^3.$$

However,  $y^4 \neq x^3$  yields a contradiction and so no such  $\phi$  exists.

- (b) Let  $\phi : M \rightarrow R$  be a  $R$ -module homomorphism and let  $a = \phi(x^2)$  and  $b = \phi(y^3)$ . Then as above, we must have that  $y^3a = x^2b$ . This means that  $y^3 \mid b$  and so there exists  $c \in k[x, y]$  such that  $y^3c = b$ . Then  $y^3a = x^2b = x^2y^3c$  implies that  $a = x^2c$ . So  $\phi(x^2) = x^2c$  and  $\phi(y^3) = y^3c$ , i.e.  $\phi(1) = c$ . This implies that  $\text{Hom}(\langle x^2, y^3 \rangle, k[x, y]) \simeq k[x, y]$  as  $k[x, y]$ -modules as we can choose any  $c$  and such  $c$  is unique.

□

**Solution: [CLO05] Ex. 5.1.9:**

- (a) Follows immediately from **<< Exercise 1. >>**
- (b) Clearly  $\langle f_1, f_2 \rangle \subseteq M$ . Now let  $(X_1, X_2, X_3) \in M$ . Thus,  $X_1 + x^2X_2 + (y - 2)X_3 = 0$  so that  $X_1 = -x^2X_2 - (y - 2)X_3$  which immediately implies that  $(X_1, X_2, X_3) = (-x^2X_2 - (y - 2)X_3, X_2, X_3)$ . This means that  $(X_1, X_2, X_3) \in \langle f_1, f_2 \rangle$  and so  $\langle f_1, f_2 \rangle = M$  as desired.
- (c) **<< Strightforward genearlization of above argument. >>**

□

**Solution:** [CLO05] Ex. 5.1.10:

(a) We know that  $\langle a_1, \dots, a_m \rangle = R$  if and only if  $1 \in \langle a_1, \dots, a_m \rangle$ . So we show that the morphism is surjective if and only if  $1 \in \langle a_1, \dots, a_m \rangle$ . If the morphism is surjective, then there exists  $f = \begin{pmatrix} f_1 & \dots & f_m \end{pmatrix}^\top$  such that  $a_1 f_1 + \dots + a_m f_m = 1$  and so  $1 \in \langle a_1, \dots, a_m \rangle$ . Now suppose that  $1 \in \langle a_1, \dots, a_m \rangle$ . Choose  $g_1, \dots, g_m \in R$  such that  $1 = a_1 g_1 + \dots + a_m g_m$ . Let  $r \in R$ . Define  $f_i = r g_i$  for  $1 \leq i \leq m$ . Then clearly for  $f = \begin{pmatrix} f_1 & \dots & f_m \end{pmatrix}^\top$  we have that  $f$  maps to  $r$  and so the morphism is onto.

(b) This follows from the fact that nonzero constants in  $k[\bar{x}]$  are invertible.

(c) We have that

$$\frac{1}{2}(x + xy) + \left(-\frac{x}{2} + 1\right)(1 - y) + (-y)(1 + x) = 1.$$

(d) << Gave up. >>

(e) We see that  $a_3 h_1 - a_2 h_2 + a_1 h_3 = 0$  showing a linear dependence. Consider  $\langle h_1, h_2 \rangle$ . Notice that for every  $\begin{pmatrix} X_1 & X_2 & X_3 \end{pmatrix}^\top \in \langle h_1, h_2 \rangle$  we must have that  $a_1 \mid X_2$  and  $a_2 \mid X_3$ . Clearly this is not true for  $h_3$  and so  $h_3 \notin \langle h_1, h_2 \rangle$  and so  $\langle h_1, h_2 \rangle \neq M$ . Showing  $\langle h_1, h_3 \rangle, \langle h_2, h_3 \rangle \neq M$  is similar.

□

**Solution:** [CLO05] Ex. 5.1.11: We have that

$$\begin{aligned} 3f_1 + 2f_2 + 2f_3 &= 3f_1 + (1+x)f_2 + (1-x)f_2 + 2f_3 \\ &= (1-x)f_2 + 2f_3 \\ &= \frac{1}{2}((2-x)f_2 + 4f_3) \\ &= \frac{1}{2} \cdot 0 = 0. \end{aligned}$$

□

**Solution:** [CLO05] Ex. 5.1.17: We saw in ?? (c) that  $\text{Syz}(f_1, f_2, f_3) = \left\langle \begin{pmatrix} -z & y & -x \end{pmatrix} \right\rangle$ . Since  $M = \langle f_1, f_2, g_3 \rangle$  has 3 generators and  $\text{Syz}(f_1, f_2, f_3)$  has one generator, we have that our presentation matrix  $A$  is  $3 \times 1$ . Then,  $\varphi: M \rightarrow R^l$  is given by an  $l \times 3$  matrix  $B = (b_{i,j})$ . The condition from [CLO05, §5.1, Proposition 1.11] stating that  $BA = 0$  means that for all  $1 \leq i \leq l$  we have that  $-zb_{i,1} + yb_{i,2} - xb_{i,3} = 0$ . This completely characterizes all morphisms  $\varphi: M \rightarrow R^l$ .

□

**Solution: [CLO05] Ex. 5.1.18:** Let  $c = (c_1 \ \dots \ c_l)$  and  $d = (d_1 \ \dots \ d_l)$ . Suppose that  $\sum_{i=1}^l c_i f_i = \sum_{i=1}^l d_i f_i$ . We have that  $\sum_{i=1}^l c_i \varphi(f_i) = Bc$  and  $\sum_{i=1}^l d_i \varphi(f_i) = Bd$ . Showing that  $\varphi$  is well-defined is equivalent to showing that  $Bc = Bd$  for all  $c, d$ . Equivalently, we want to show that  $Bx = 0$  for all  $x \in \text{Syz}(f_1, \dots, f_l)$ . Recall that the columns of  $A$  are the generators of  $\text{Syz}(f_1, \dots, f_n)$ . Thus,  $\varphi$  is well-defined if and only if  $BA = 0$ .  $\square$

**Solution: [CLO05] Ex. 5.1.19:**

- (a) Let  $c = (c_1 \ \dots \ c_s)$ . If  $\sum_{i=1}^s c_i f_i = 0$ , then  $Ac = 0$ . But  $A$  is invertible and so  $c = 0$  meaning that  $\{f_1, \dots, f_s\}$  forms a basis.
- (b) Suppose that  $N \simeq R^s$ . Then there exists an isomorphism  $\varphi: N \rightarrow R^s$ . This is given by a matrix  $A$  where  $A$  is invertible as  $\varphi$  is an isomorphism. We have a standard basis  $\{e_1, \dots, e_s\}$  for  $R^s$ . Define  $f_i$  as in (a). We saw that this forms a basis for  $N$  and so  $N$  is free.

Now suppose that  $N$  is free with basis  $\{f_1, \dots, f_s\}$ . Let  $\varphi: N \rightarrow R^s$  be given by  $f_i \mapsto e_i$  and extend by linearity. This is well defined, linear, surjective, and injective by linear independence of the basis  $\{e_1, \dots, e_s\}$ . Thus,  $N \simeq R^s$ .

$\square$

## 5.2 Monomial Orders and Gröbner Bases for Modules

**Solution:** [CLO05] Ex. 5.2.6:

- (a) Follows immediately from the distributivity of multiplication in  $S = k[x_1, \dots, x_n, X_1, \dots, X_m]$ .
- (b) Follows immediately from the distributivity of multiplication in  $S$  and the fact that  $R = k[x_1, \dots, x_n]$  contains no monomials containing any of the  $X_j$ .
- (c) Consider  $f_i$ , one of the generators of  $M$ . Then there exists  $r_i \in R$  such that  $f_i = \sum_{i=1}^s r_i e_i$ . We have that  $F_i = \varphi(f_i) = \sum_{i=1}^s r_i X_i$  and so each  $F_i$  is an element of  $S_1$ . By  $R$ -linearity, this shows that  $\varphi(M) \subseteq \langle F_1, \dots, F_s \rangle S \cap S_1$ . Now suppose that  $f \in \langle F_1, \dots, F_s \rangle S \cap S_1$ . Then as  $f \in \langle F_1, \dots, F_s \rangle S$ , there exists  $r_i \in S$  such that  $f = \sum_{i=1}^s r_i F_i$ . Note that each  $F_i \in S_1$ . Thus, as polynomial rings over a field are a domain and  $f \in S_1$ , we must have that each  $r_i \in R$  instead of just  $r_i \in S$ . Thus,  $f = \varphi(\sum_{i=1}^s r_i f_i)$  as desired.
- (d) The fact that the given modification of Buchberger's Algorithm works follows from the fact that in (c), we know that the image of  $M$  in  $S$  under  $\varphi$  is contained in  $S_1$  and so any other  $S$ -polynomials not in  $S_1$  are irrelevant as they do not appear in the image of  $M$ .

□

**Solution:** [CLO05] Ex. 5.2.7: Recall that the only monomial ordering on  $R = k[x]$  is  $1 < x < x^2 < \dots$ . Let  $M$  be some submodule of  $R^m$  and  $G$  a Gröbner basis for  $M$ . Without loss of generality, say  $G$  is monic and reduced. Suppose there were elements of  $G$  whose leading terms both contain some  $e_i$ , say  $x^a e_i$  and  $x^b e_i$ . Then either  $x^a \mid x^b$  or  $x^b \mid x^a$ . So  $G$  is not reduced, a contradiction and so no such pair of elements can exist. Via similar logic, if an element of  $G$  has a term which contains  $e_i$ , then the  $i$ -th component of every other element of  $G$  must be zero. In particular, this shows that every monic, reduced Gröbner basis of a submodule of  $R^m$  must have  $\leq m$  elements. Thus, by the uniqueness of monic, reduced Gröbner bases, there are at most  $2^m$  submodules of  $R^m$ . □

### 5.3 Computing Syzygies

**Solution:** [CLO05] Ex. 5.3.1: We have that

$$\mathbf{s}_{ij} \cdot (g_1 \ \cdots \ g_s)^\top = \frac{x^{\gamma_{ij}}}{\text{LT}(g_i)} g_i - \frac{x^{\gamma_{ij}}}{\text{LT}(g_j)} g_j - \sum_{k=1}^s a_{ijk} g_k = S(g_i, g_j) - S(g_i, g_j) = 0.$$

Thus,  $\mathbf{s}_{ij} \in \text{Syz}(g_1, \dots, g_s)$ . □

**Solution:** [CLO05] Ex. 5.3.7: Suppose  $h_0 \in I \cap J$ . Then there exists  $h_1, \dots, h_t, h_{t+1}, \dots, h_{t+s}$  such that  $h_0 = \sum_{i=1}^t h_i f_i$  and  $h_0 = \sum_{j=1}^s h_{t+j} g_j$ . Then, it is easy to see that

$$\mathbf{0} = h_0 \mathbf{v}_0 + \sum_{i=1}^t -h_i \mathbf{v}_i + \sum_{j=1}^s h_{t+j} \mathbf{v}_{t+j}$$

and so  $(h_0 \ h_1 \ \cdots \ h_{t+s})^\top \in \text{Syz}(\mathbf{v}_0, \mathbf{v}_1, \dots, \mathbf{v}_t, \mathbf{v}_{t+1}, \dots, \mathbf{v}_{t+s}) \subseteq R^{t+s+1}$ . □

**Solution:** [CLO05] Ex. 5.3.10:

- (a) Recall from [CLO05, << Exercise 1.3.12 >>] that if  $\{g_1, \dots, g_t\}$  is Gröbner basis for  $I \cap \langle h \rangle$  then  $I : \langle h \rangle$  has a Gröbner basis given by  $\langle g_1/h, \dots, g_t/h \rangle$ . Given  $I = \langle f_1, \dots, f_s \rangle$  and  $h$ , first compute the generators of the syzygy modules  $\text{Syz}(\mathbf{v}_0, \mathbf{v}_1, \dots, \mathbf{v}_s, \mathbf{v}_{s+1})$  where

$$\begin{aligned} \mathbf{v}_0 &= \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \\ \mathbf{v}_1 &= \begin{pmatrix} f_1 \\ 0 \end{pmatrix}, \dots, \mathbf{v}_s = \begin{pmatrix} f_s \\ 0 \end{pmatrix}, \\ \mathbf{v}_{s+1} &= \begin{pmatrix} 0 \\ h \end{pmatrix}. \end{aligned}$$

By [CLO05, §5.3, Proposition 3.11], the first components of these generators are the generators  $\langle g_1, \dots, g_t \rangle$  of  $I \cap \langle h \rangle$ . Furthermore, if  $(g_i \ h_{i,1} \ \cdots \ h_{i,s} \ h_{i,s+1})^\top$  is the syzygy generator witnessing  $g_i$ , then we can compute  $g_i/h$  without division. To see this, study the second row of the following syzygy relation:

$$\mathbf{0} = g_i \mathbf{v}_0 + \mathbf{v}_1 h_{i,1} + \cdots + \mathbf{v}_s h_{i,s} + \mathbf{v}_{s+1} h_{i,s+1}$$

This means  $0 = g_i + h \cdot h_{i,s+1}$  and so  $g_i/h = -h_{i,s+1}$ . Thus, we can recover the generators of  $I : \langle h \rangle$  without doing polynomial division.

- (b) << Is there anything better >> than repeating [CLO05, §5.3, Proposition 3.11] multiple times?

□

**Solution:** [CLO05] Ex. 5.3.12: Let  $f_1, f_2 \in k[\bar{x}]$  be nonzero. Then  $\text{Syz}(f_1, f_2) \subseteq k[\bar{x}]^2$  is the set of  $\begin{pmatrix} a_1 & a_2 \end{pmatrix}^\top$  such that  $a_1 f_1 + a_2 f_2 = 0$ . Let  $g = \gcd(f_1, f_2)$  and let  $g_1 = \frac{f_2}{g}$  and  $g_2 = \frac{f_1}{g}$ . Then it is easy to see that  $\begin{pmatrix} g_1 & -g_2 \end{pmatrix}^\top$  generates  $\text{Syz}(f_1, f_2)$ . Indeed, suppose that  $\begin{pmatrix} a_1 & a_2 \end{pmatrix}^\top \in \text{Syz}(f_1, f_2)$ . Then since  $a_1 f_1 + a_2 f_2 = 0$ , we have that  $a_1 f_1 = -a_2 f_2$  and so  $f_2 \mid a_1 f_1$ . Thus,  $g_1 = \frac{f_2}{g} \mid a_1$ . Similarly, we get that  $g_2 = \frac{f_1}{g} \mid -a_2$ . Thus,  $\begin{pmatrix} a_1 & a_2 \end{pmatrix}^\top \in \left\langle \begin{pmatrix} g_1 & -g_2 \end{pmatrix}^\top \right\rangle$ . □

## 5.4 Modules over Local Rings

**Solution:** [CLO05] Ex. 5.4.1: From ??, we know that every ideal in  $k[x_1, \dots, x_n]_{\langle x_1, \dots, x_n \rangle}$  is generated by a finite set of polynomials in  $k[x_1, \dots, x_n]$ . Then the claim follows from the same proof as [CLO05, §5.2, Proposition 2.3a].  $\square$

**Solution:** [CLO05] Ex. 5.4.4:

(a) We have that  $V(M) = \{(1, 1)\} \cup \{x = 0\}$ . Given this, we see that if we remove any generator of the ideal, the set of common zeros will then include a whole new line of common zeros, thus defining a different variety. This shows that if we remove any particular generator then we no longer have the ideal  $M$  and so  $\{xy(y-1), xy(x-1), x(y-1)(x-1)\}$  is unshortenable.

(b) Let  $N = \langle xy^2 - x^2y, x^2 - x \rangle$ . We show that the generators of  $N$  are in  $M$  and vice versa, which implies that  $M = N$ :

$$\begin{aligned} xy^2 - x^2y &= xy(y-1) - xy(x-1), \\ x^2 - x &= -x(y-1)(x-1) + xy(x-1), \\ xy(y-1) &= xy^2 - x^2y + y(x^2 - x), \\ xy(x-1) &= y(x^2 - x), \\ x(y-1)(x-1) &= (y-1)(x^2 - x). \end{aligned}$$

$\square$

**Solution:** [CLO05] Ex. 5.4.6:

(a) By [CLO05, §4.3, Proposition 3.10], there exists free  $R$  modules  $L$  and  $L'$  such that  $\text{Syz}(f_1, \dots, f_t) \oplus L \simeq \text{Syz}(g_1, \dots, g_s) \oplus L'$ . Since  $\text{Syz}(g_1, \dots, g_s)$  and  $L'$  are both free, their direct sum must also be free. Thus,  $\text{Syz}(f_1, \dots, f_t)$  is projective.

(b) Since  $R$  is a free  $R$ -module, we have that  $R = \langle 1 \rangle$  and  $\text{Syz}(1) = \langle 0 \rangle$  is free. Take  $g_1 = 1$ . By (a), we have that  $\text{Syz}(f_1, \dots, f_t)$  is projective.

$\square$

## Chapter 6

# Free Resolutions

### 6.1 Presentations and Resolutions of Modules

**Solution:** [CLO05] Ex. 6.1.7:

- (a) Denote the kernel morphisms as  $k_i: \ker(\varphi_i) \rightarrow M_i$ . Note that the morphism  $\varphi_i: M_i \rightarrow \ker(\varphi_{i-1})$  is well defined as  $\text{im}(\varphi_i) = \ker(\varphi_{i-1})$ . Exactness at  $\ker(\varphi_i)$  is immediate as  $k_i$  is an inclusion morphism and thus injective. To show exactness at  $M_i$ , we want to show that  $\text{im}(k_i) = \ker(\varphi_i)$  which is immediate as  $\text{im}(k_i) = \ker(\varphi_i)$  as the inclusion map  $k_i$  is injective. Exactness at  $\ker(\varphi_{i-1})$  follows from the fact that  $\ker(\varphi_{i-1}) = \text{im}(\varphi_i)$  and obviously morphisms are surjective onto their images.
- (b) We clearly have exactness as  $\ker(\varphi_{n-1})$  as inclusion morphisms are injective. Again, let  $k_{n-1}$  be the kernel morphism  $k_{n-1}: \ker(\varphi_{n-1}) \rightarrow M_{n-1}$ . To show exactness as  $M_{n-1}$ , we want that  $\text{im}(k_i) = \ker(\varphi_{n-1})$  which is immediate again by the exactness of  $0 \rightarrow \ker(\varphi_{n-1}) \xrightarrow{k_{n-1}} M_i \xrightarrow{\varphi_{n-1}} N_i \rightarrow 0$ . For  $1 \leq i \leq n-2$ , showing exactness at  $M_i$  amounts to showing that  $\text{im}(\varphi_{i+1}) = \ker(\varphi_i)$ . This follows from exactness at  $N_{i+1} = \ker(\varphi_i)$  in the given short exact sequences. Finally, exactness at  $\text{im}(\varphi_1)$  is immediate as every morphism is surjective onto its image.
- (c) Follows from the above and discussion prior to [CLO05, §6.1, Definition 1.9].

## 6.2 Hilbert's Syzygy Theorem

**Solution:** [CLO05] Ex. 6.2.8:

- (a) If there were two elements of  $\mathcal{G}$  with leading term  $e_i$ , this would contradict the fact that  $\mathcal{G}$  is reduced.
- (b) Let  $\mathcal{G} = \{g_1, \dots, g_s\}$ . Let us study the structure of  $\mathcal{G}$  further. By (a) we know that  $s \leq t$  and that  $\text{LT}(g_j) = e_{i_j}$  for some unique  $i_j$  such that  $1 \leq i_1 < \dots < i_s \leq t$ . As  $\mathcal{G}$  is reduced, we know that no term of  $g_j$  is divisible by  $e_{i_k}$  for  $k \neq j$ . From the discussion just prior to Schreyer's Theorem [CLO05, §5.3, Theorem 5.3], we see that the expressions  $s_{ij}$  are 0 as  $\text{lcm}(\text{LT}(g_j), \text{LT}(g_k)) = \text{lcm}(e_{i_j}, e_{i_k}) = 0$  by definition for  $j \neq k$  and are also clearly 0 for  $j = k$ . Thus, as the  $s_{ij}$  form a Gröbner basis for  $\text{Syz}(\mathcal{G})$ , we must have that  $\text{Syz}(\mathcal{G}) = 0$ .
- (c) Free modules are exactly the modules with trivial syzygy modules.

□

**Solution:** [CLO05] Ex. 6.2.10:

- (a) Let  $R = k[x_1, \dots, x_5]$ . For  $I_2$ , we have the exact sequence

$$0 \rightarrow R \xrightarrow{\varphi_2} R^2 \xrightarrow{\varphi_1} I_2 \rightarrow 0$$

where  $\varphi_2(1) = (x_2, -x_1)$  and  $\varphi_1(a, b) = ax_1 + bx_2$ . For  $I_3$ , we have the exact sequence

$$0 \rightarrow R \xrightarrow{\varphi_3} R^3 \xrightarrow{\varphi_2} R^3 \xrightarrow{\varphi_1} I_3 \rightarrow 0.$$

Here,  $\varphi_3(1) = (x_1, -x_2, x_3)$ . Then  $\varphi_2(a, 0, 0) = (0, -ax_3, ax_2)$ ,  $\varphi_2(0, b, 0) = (-bx_3, 0, bx_1)$ , and  $\varphi_2(0, 0, c) = (-cx_2, cx_1, 0)$ . Finally,  $\varphi_1(a, b, c) = ax_1 + bx_2 + cx_3$ . **<< TODO: Further examples with computer. >>**

- (b) Now let  $R = k[x_1, \dots, x_n]$ . First,  $\varphi_1: R^m \rightarrow I_m$  is given by  $(r_1, \dots, r_m) \mapsto r_1x_1 + \dots + r_mx_m$  which is clearly surjective. Next, the map  $\varphi_m: R = R^{\binom{m}{m}} \rightarrow R^{\binom{m}{m-1}} = R^m$  is given by  $1 \mapsto (x_1, -x_2, \dots, (-1)^{m-1}x_m)$  which is injective as  $R$  is a domain. A tedious check yields that for  $1 < k < m$ ,  $\varphi_{k-1} \circ \varphi_k = 0$  and so  $\text{im}(\varphi_k) \subseteq \ker(\varphi_{k-1})$ .

**<< STUCK: >>** How do I show that  $\ker(\varphi_{k-1}) \subseteq \text{im}(\varphi_k)$ ?

□

### 6.3 Graded Resolutions

**Solution:** [CLO05] Ex. 6.3.3:

- (a) Clearly  $R_t$  is a finite dimensional  $k$ -vector space with a basis given by monomials. Then by similar logic,  $R(-d)_t$  is a finite dimensional  $k$ -vector space. If  $M = \langle f_1, \dots, f_m \rangle$  is a finitely generated  $R$ -module, then we have a graded surjection

$$\varphi: R(-d_1) \oplus \dots \oplus R(-d_m) \rightarrow M.$$

Thus, we must have that  $M_t$  is finite dimensional as a  $k$ -vector space for all  $t$ . Furthermore,  $\varphi$  is a graded homomorphism of degree 0. So for all  $t$ ,  $\varphi(R(-d_1)_t \oplus \dots \oplus R(-d_m)_t) = M_t$  by surjectivity. However,  $R(-d_i)_t = R_{t-d_i} = 0$  whenever  $t - d_i < 0$ , meaning  $t < d_i$ . Thus,  $M_t = 0$  whenever  $t < \min\{d_1, \dots, d_m\}$ .

- (b) We already know that  $\psi(M_t) \subseteq M_t$ . If  $\psi$  is an isomorphism, it is surjective and so for all  $y \neq 0 \in M_t$ , there exists  $x \in M$  such that  $\psi(x) = y$ . But we know that  $x \in M_t$  as  $\psi(M_t) \subseteq M_t$  and for all  $s \neq t$ ,  $\psi(M_s) \cap M_t = \{0\}$ . Thus,  $\psi: M_t \rightarrow M_t$  is surjective. Now suppose that  $\psi: M_t \rightarrow M_t$  is surjective for all  $t$ . Clearly this implies that  $\psi: M \rightarrow M$  is surjective. Since  $M_t$  is a finite dimensional  $k$ -vector space,  $\psi: M_t \rightarrow M_t$  must be an isomorphism. Now let  $x \in M_t$  such that  $\psi(x) = 0$ . If  $x \in M_t$ , then since  $\psi: M_t \rightarrow M_t$  is an isomorphism, we must have that  $\psi(x) = 0 \in M_t$  and so  $x = 0$ . Thus,  $\psi$  is an isomorphism. Since  $\psi$  is surjective if and only if  $\psi: M_t \rightarrow M_t$  is surjective for all  $t$ , we have that  $\psi$  is an isomorphism if and only if it is a surjection.

□

**Solution:** [CLO05] Ex. 6.3.8: We first show  $a. \implies c.$  **<< STUCK. >>** Then  $c. \implies b. \implies a.$  is trivial and overall we have equivalence. □

**Solution:** [CLO05] Ex. 6.3.10: Consider the resolution

$$\dots \rightarrow F_\ell \xrightarrow{\varphi_\ell} F_{\ell-1} \rightarrow \dots \rightarrow F_0 \rightarrow M \rightarrow 0$$

Suppose that for all  $\ell \geq 0$ ,  $\varphi_\ell$  takes the standard basis of  $F_\ell$  to a minimal generating set of  $\text{im}(\varphi_\ell)$ . Let  $\ell \geq 1$  and consider the matrix  $A_\ell$  of  $\varphi_\ell: F_\ell \rightarrow F_{\ell-1}$ . Let  $F_\ell$  have standard generating set  $\{e_1, \dots, e_m\}$  so that  $\{\varphi_\ell(e_1), \dots, \varphi_\ell(e_m)\}$  is a minimal generating set for  $\text{im}(\varphi_\ell)$ . Let  $\{f_1, \dots, f_n\}$  be the standard generating set for  $F_{\ell-1}$ . Then  $A_\ell$  is given by a matrix  $(a_{i,j})_{1 \leq i, j \leq n}$  such that We want to show that every non-zero entry of  $A_\ell$  has positive degree. Suppose not, say that  $a_{i,j}$  is some nonzero constant  $c \in k$ . **<< Sketch: >>** You can then use this non-zero constant to express  $\varphi_\ell(e_j)$  terms of the other vectors contradicting minimality. □

## 6.4 Hilbert Polynomials and Geometric Applications

Solution: [CLO05] Ex. 6.4.1:

$$H_{M(d)}(t) = \dim_k M(d)_t = \dim_k M_{t+d} = H_M(t+d).$$

□

Solution: [CLO05] Ex. 6.4.2:

(a)

$$H_{M \oplus N}(t) = \dim_k (M \oplus N)_t = \dim_k M_t \oplus N_t = \dim_k M_t + \dim_k N_t = H_M(t) + H_N(t).$$

(b) Note that for all  $t \in \mathbb{Z}$ ,  $\alpha$  and  $\beta$  restrict to  $k$ -vector space morphisms  $\alpha: M_t \rightarrow P_t$  and  $\beta: P_t \rightarrow N_t$ . In particular, we have for all  $t \in \mathbb{Z}$  the following short exact sequence:

$$0 \rightarrow M_t \xrightarrow{\alpha} P_t \xrightarrow{\beta} N_t \rightarrow 0.$$

We know that for  $k$ -vector spaces, all such short exact sequences split so that  $P_t \simeq M_t \oplus N_t$ . Thus, by (a) we have that  $H_P = H_M + H_N$ .

(c) Apply (b) to the short exact sequence

$$0 \rightarrow M \rightarrow M \oplus N \rightarrow N \rightarrow 0$$

with the obvious maps.

□

**Solution:** [CLO05] Ex. 6.4.3:

(a) Let  $I := \langle x^2 - xz, xy, y^2 - yz \rangle$ . Clearly  $V \subseteq V(I)$  so that  $I(V) \supseteq I(V(I)) = \sqrt{I}$ . Now suppose that  $[a : b : c] \in V(I)$ . We have that  $a^2 = ac$ . First, suppose that  $a = 0$  so that  $b^2 = bc$ . Again, we have two cases. If  $b = 0$  then  $c$  is free and so  $[a : b : c] = [0 : 0 : 1]$ . On the other hand, if  $b \neq 0$  we have that  $b = c$  and so  $[a : b : c] = [0 : 1 : 1]$ . Otherwise,  $a \neq 0$  so that  $a = c$ . Thus, we must have that  $b = 0$  so that  $\langle a : b : c \rangle = [1 : 0 : 1]$ . This yields that  $V(I) \subseteq V$  and thus  $I(V) \subseteq I(V(I)) = \sqrt{I}$ . Overall, we have that  $I(V) = \sqrt{I}$ . A quick check in SageMath yields that  $I = \sqrt{I}$  and so  $I(V) = I$  as desired.

(b) A quick check in SageMath computes the following graded free resolution:

$$0 \rightarrow R(-3)^2 \xrightarrow{\begin{pmatrix} -x & 0 \\ y-z & -x+z \\ 0 & y \end{pmatrix}} R(-2)^3 \xrightarrow{\begin{pmatrix} y^2-yz & xy & x^2-xz \end{pmatrix}} I \rightarrow 0.$$

Compare this to the free resolution of  $\tilde{I} = \langle x^2 - x, xy, y^2 - y \rangle$

$$0 \rightarrow R^2 \xrightarrow{\begin{pmatrix} -x & 0 \\ y-1 & -x+1 \\ 0 & y \end{pmatrix}} R^3 \xrightarrow{\begin{pmatrix} y^2-y & xy & x^2-x \end{pmatrix}} \tilde{I} \rightarrow 0.$$

We see that  $\tilde{I}$  is the dehomogenization of the ideal  $I$  obtained by setting  $z = 1$ . Similarly, this free resolution of  $\tilde{I}$  is obtained by setting  $z = 1$  in all the matrices defining the maps.

(c) From the graded free resolution, we see that

$$\dim_k I_t = \dim_k (R(-2)^3)_t - \dim_k (R(-3)^2)_t = 3 \binom{t}{2} - 2 \binom{t-1}{2}.$$

Thus, we have that

$$H_{R/I}(t) = \dim_k R_t - \dim_k I_t = \binom{t+2}{2} - 3 \binom{t}{2} + 2 \binom{t-1}{2} = \begin{cases} 1 & t = 0, \\ 3 & t \geq 1. \end{cases}$$
